

# Deletion from **Red-Black** Trees

# Setting Up Deletion

As with binary search trees, we can always delete a node that has at least one external child

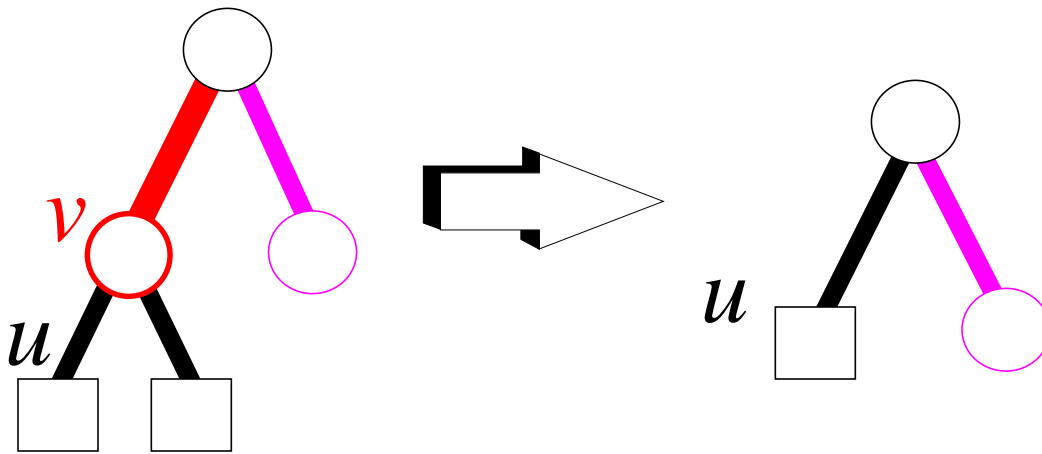

If the key to be deleted is stored at a node that has no external children, we move there the key of its inorder predecessor (or successor), and delete that node instead

**Example:** to delete key 7, we move key 5 to node  $u$ , and delete node  $v$

# Deletion Algorithm

1. Remove  $v$  with a `removeAboveExternal` operation
2. If  $v$  was **red**, color  $u$  black. Else, color  $u$  *double black*.

3. While a *double black* edge exists, perform one of the following actions ...

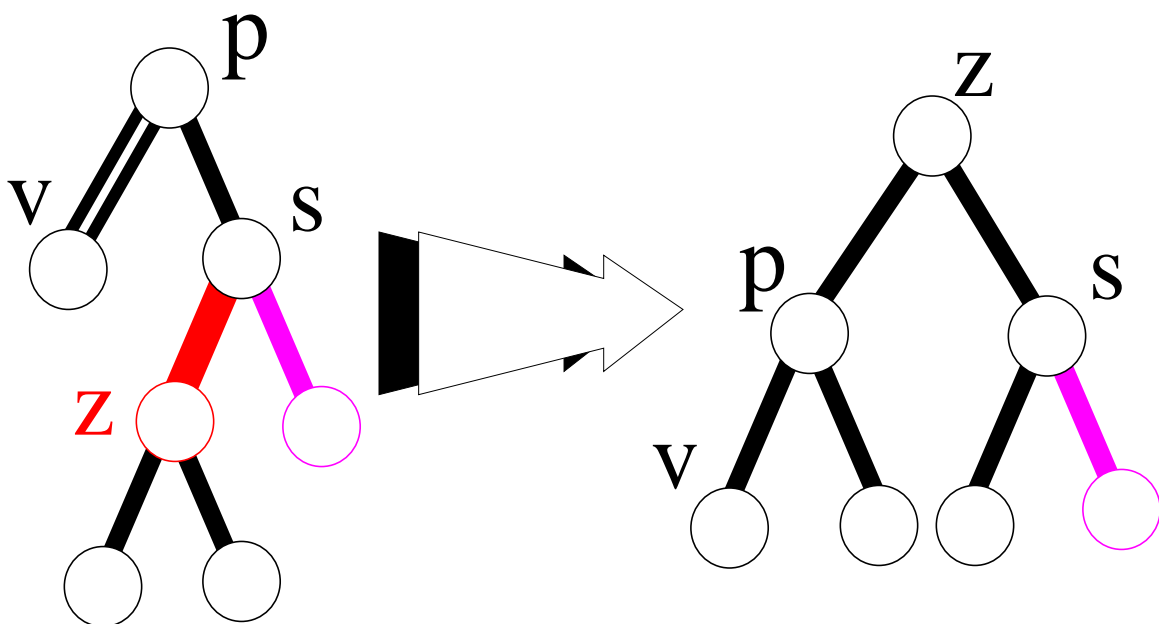

# How to Eliminate the Double Black Edge

- The intuitive idea is to perform a “*color compensation*”
- Find a red edge nearby, and change the pair ( *red* , *double black* ) into ( *black* , *black* )
- As for insertion, we have two cases:
  - *restructuring*, and
  - *recoloring (demotion)*, inverse of promotion)
- Restructuring resolves the problem locally, while *recoloring* may propagate it two levels up
- Slightly more complicated than insertion, since two restructurings may occur (instead of just one)

# Case 1: black sibling with a red child

- If sibling is **black** and one of its children is **red**, perform a *restructuring*

# (2,4) Tree Interpretation

## Case 2: black sibling with black children

- If sibling and its children are **black**, perform a *recoloring*
- If parent becomes **double black**, *continue* upward

# (2,4) Tree Interpretation

## Case 3: red sibling

- If sibling is red, perform an *adjustment*
- Now the sibling is **black** and one the of previous cases applies
- If the next case is recoloring, there is no propagation upward (parent is now **red**)

# How About an Example?

Remove 9

# Example

## What do we know?

- Sibling is black with black children

## What do we do?

- Recoloring

# Example

## Delete 8

- no double black

# Example

## Delete 7

- Restructuring

# Example

# Example

# Time Complexity of Deletion

Take a guess at the time complexity of deletion in a **red**-black tree . . .

$O(\log N)$

**What else could it be?!**

# Colors and Weights

**Color**

**Weight**

red

0

black

1

**double black**

**2**

**Every root-to-leaf path has the same weight**

**There are no two consecutive red edges**

- Therefore, the length of any root-to-leaf path is at most twice the weight

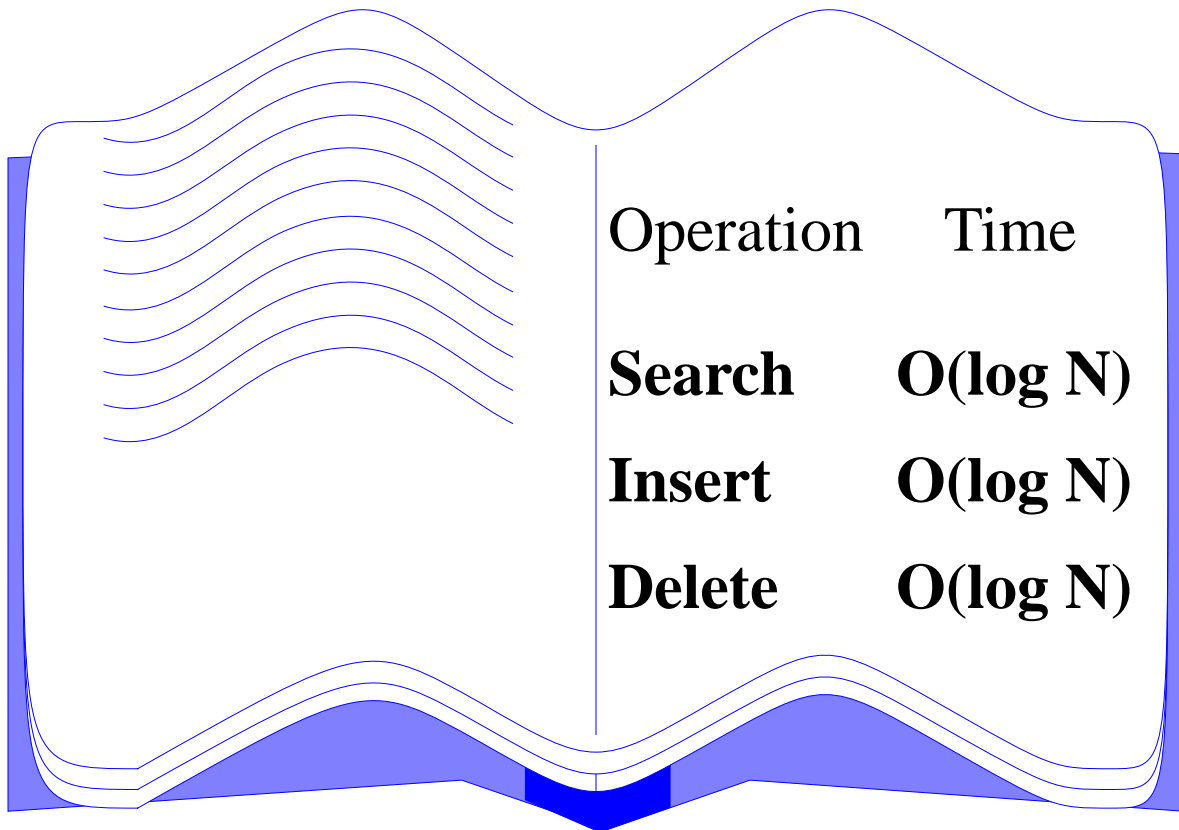

# Bottom-Up Rebalancing of **Red-Black** Trees

- An insertion or deletion may cause a local *perturbation* (two consecutive **red** edges, or a **double-black** edge)
- The perturbation is either
  - *resolved locally* (restructuring), or
  - *propagated* to a higher level in the tree by recoloring (promotion or demotion)
- $O(1)$  time for a restructuring or recoloring
- At most one restructuring per insertion, and at most two restructurings per deletion
- $O(\log N)$  recolorings
- Total time:  $O(\log N)$

# Red-Black Trees

Operation	Time
<b>Search</b>	<b><math>O(\log N)</math></b>
<b>Insert</b>	<b><math>O(\log N)</math></b>
<b>Delete</b>	<b><math>O(\log N)</math></b>
