

# PRIORITY QUEUES

- The Priority Queue Abstract Data Type
- Implementing A Priority Queue With a Sequence

# Keys and Total Order Relations

- A Priority Queue ranks its elements by *key* with a *total order* relation
- Keys:
  - Every element has its own key
  - Keys are not necessarily unique
- Total Order Relation
  - Denoted by  $\leq$
  - **Reflexive:**  $k \leq k$
  - **Antisymmetric:** if  $k_1 \leq k_2$  and  $k_2 \leq k_1$ , then  $k_1 \leq k_2$
  - **Transitive:** if  $k_1 \leq k_2$  and  $k_2 \leq k_3$ , then  $k_1 \leq k_3$
- A Priority Queue supports these fundamental methods:
  - `insertItem(k, e)` // element  $e$ , key  $k$
  - `removeMinElement()` // return and remove the // item with the smallest key

# Sorting with a Priority Queue

- A Priority Queue  $P$  can be used for sorting by inserting a set  $S$  of  $n$  elements and calling `removeMinElement()` until  $P$  is empty:

**Algorithm** `PriorityQueueSort( $S, P$ )`:

*Input:* A sequence  $S$  storing  $n$  elements, on which a total order relation is defined, and a Priority Queue  $P$  that compares keys with the same relation  
*Output:* The Sequence  $S$  sorted by the total order relation

```
while ! $S$ .isEmpty() do
     $e \leftarrow S$ .removeFirst()
     $P$ .insertItem( $e, e$ )
while  $P$  is not empty do
     $e \leftarrow P$ .removeMinElement()
     $S$ .insertLast( $e$ )
```

# The Priority Queue ADT

- A priority queue  $P$  must support the following methods:
  - **size()**:  
Return the number of elements in  $P$   
**Input:** None;      **Output:** integer
  - **isEmpty()**:  
Test whether  $P$  is empty  
**Input:** None;      **Output:** boolean
  - **insertItem( $k, e$ )**:  
Insert a new element  $e$  with key  $k$  into  $P$   
**Input:** Objects  $k, e$  **Output:** None
  - **minElement()**:  
Return (but don't remove) an element of  $P$  with smallest key; an error occurs if  $P$  is empty.  
**Input:** None;      **Output:** Object  $e$

# The Priority Queue ADT (contd.)

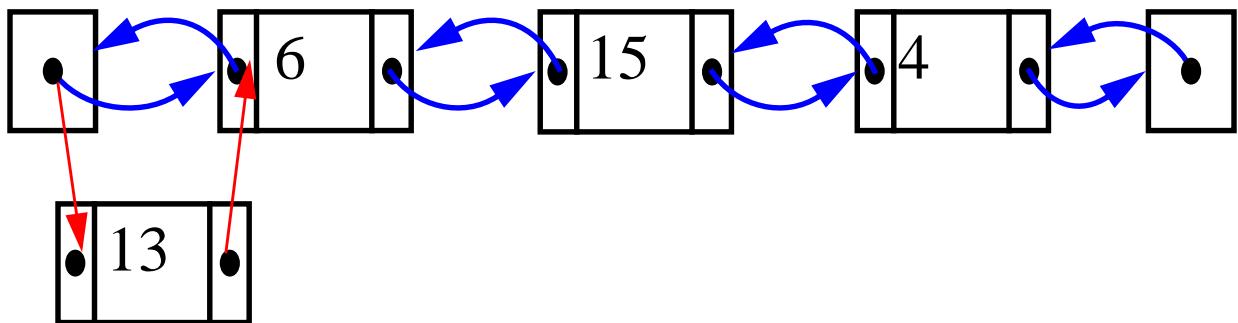

- **minKey():**  
Return the smallest key in  $P$ ; an error occurs if  $P$  is empty  
**Input:** None;      **Output:** Object  $k$
- **removeMinElement():**  
Remove from  $P$  and return an element with the smallest key; an error condition occurs if  $P$  is empty.  
**Input:** None;      **Output:** Object  $e$

# Comparators

- The most general and reusable form of a priority queue makes use of **comparator** objects.
- Comparator objects are external to the keys that are to be compared and compare two objects.
- When the priority queue needs to compare two keys, it uses the comparator it was given to do the comparison.
- Thus a priority queue can be general enough to store any object.
- The comparator ADT includes:
  - `isLessThan(a, b)`
  - `isLessThanOrEqualTo(a,b)`
  - `isEqualTo(a, b)`
  - `isGreaterThan(a,b)`
  - `isGreaterThanOrEqualTo(a,b)`
  - `isComparable(a)`

# Implementation with an Unsorted Sequence

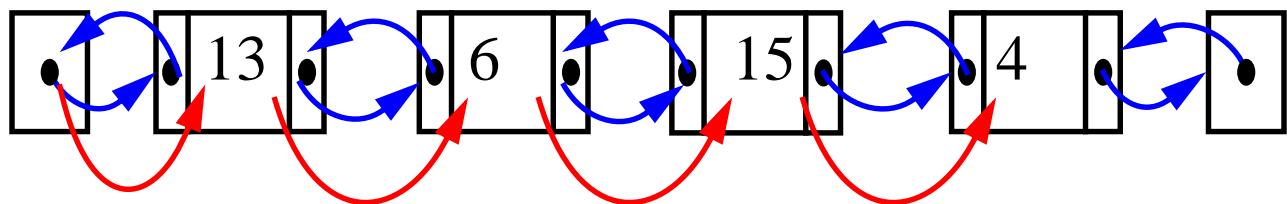

- Let's try to implement a priority queue with an unsorted sequence  $S$ .
- The elements of  $S$  are a composition of two elements,  $k$ , the key, and  $e$ , the element.
- We can implement `insertItem()` by using `insertFirst()` of the sequence. This would take  $O(1)$  time.

- However, because we always `insertFirst()`, despite the key value, our sequence is not ordered.

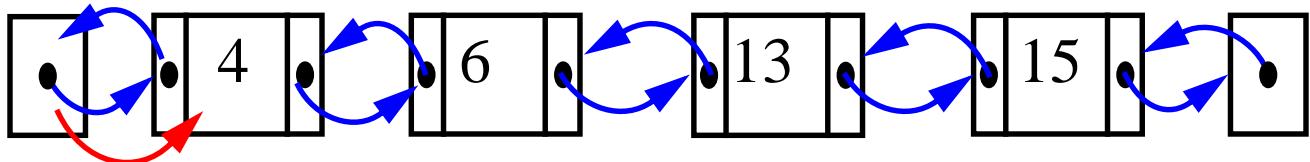

# Implementation with an Unsorted Sequence (contd.)

- Thus, for methods such as `minElement()`, `minKey()`, and `removeMinElement()`, we need to look at all elements of  $S$ . The worst case time complexity for these methods is  $O(n)$ .

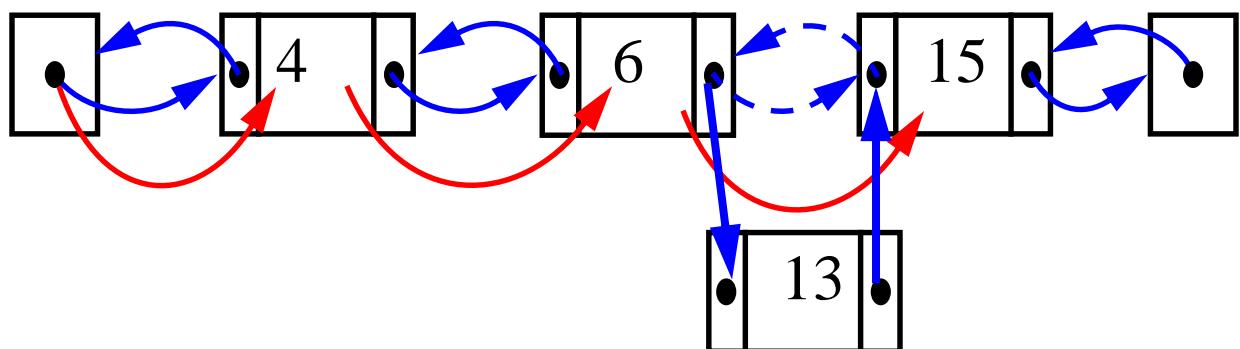

# Implementation with a Sorted Sequence

- Another implementation uses a sequence  $S$ , sorted by keys, such that the first element of  $S$  has the smallest key.
- We can implement `minElement()`, `minKey()`, and `removeMinElement()` by accessing the first element of  $S$ . Thus these methods are  $O(1)$  (assuming our sequence has an  $O(1)$  front-removal)

- However, these advantages comes at a price. To implement `insertItem()`, we must now scan through the entire sequence. Thus `insertItem()` is  $O(n)$ .

# Implementation with a Sorted Sequence(contd.)

```
public class SequenceSimplePriorityQueue
implements SimplePriorityQueue {

    //Implementation of a priority queue
    // using a sorted sequence

    protected Sequence seq = new NodeSequence();
    protected Comparator comp;
    // auxiliary methods

    protected Object extractKey (Position pos) {
        return ((Item)pos.element()).key();
    }

    protected Object extractElem (Position pos) {
        return ((Item)pos.element()).element();
    }

    protected Object extractElem (Object key) {
        return ((Item)key).element();
    }

    // methods of the SimplePriorityQueue ADT

    public SequenceSimplePriorityQueue (Comparator c) {
        this.comp = c; }

    public int size () {return seq.size(); }
```

# Implementation with a Sorted Sequence(contd.)

```
public boolean isEmpty () { return seq.isEmpty(); }

public void insertItem (Object k, Object e) throws
InvalidKeyException {
    if (!comp.isComparable(k))
        throw new InvalidKeyException("The key is not
valid");
    else
        if (seq.isEmpty())
            seq.insertFirst(new Item(k,e));
        else
            if (comp.isGreaterThan(k,extractKey(seq.last())))
                seq.insertAfter(seq.last(),new Item(k,e));
            else {
                Position curr = seq.first();
                while (comp.isGreaterThan(k,extractKey(curr)))
                    curr = seq.after(curr);
                seq.insertBefore(curr,new Item(k,e));
            }
}
```

# Implementation with a Sorted Sequence(contd.)

```
public Object minElement () throws  
EmptyContainerException {  
    if (seq.isEmpty())  
        throw new EmptyContainerException("The priority  
        queue is empty");  
    else  
        return extractElem(seq.first());  
}
```

# Selection Sort

- Selection Sort is a variation of PriorityQueueSort that uses an unsorted sequence to implement the priority queue P.
- **Phase 1**, the insertion of an item into P takes  $O(1)$  time.
- **Phase 2**, removing an item from P takes time proportional to the number of elements in P

	Sequence $S$	Priority Queue $P$
Input	(7, 4, 8, 2, 5, 3, 9)	()
Phase 1:		
(a)	(4, 8, 2, 5, 3, 9)	(7)
(b)	(8, 2, 5, 3, 9)	(7, 4)
...	...	...
(g)	()	(7, 4, 8, 2, 5, 3, ,9)
Phase 2:		
(a)	(2)	(7, 4, 8, 5, 3, 9)
(b)	(2, 3)	(7, 4, 8, 5, 9)
(c)	(2, 3, 4)	(7, 8, 5, 9)
(d)	(2, 3, 4, 5)	(7, 8, 9)
(e)	(2, 3, 4, 5, 7)	(8, 9)
(f)	(2, 3, 4, 5, 7, 8)	(9)
(g)	(2, 3, 4, 5, 7, 8, 9)	()

# Selection Sort (cont.)

- As you can tell, a bottleneck occurs in Phase 2. The first removeMinElement operation take  $O(n)$ , the second  $O(n-1)$ , etc. until the last removal takes only  $O(1)$  time.
- The total time needed for phase 2 is:

$$O(n + (n - 1) + \dots + 2 + 1) \equiv O\left(\sum_{i=1}^n i\right)$$

- By a common proposition:

$$\sum_{i=1}^n i = \frac{n(n+1)}{2}$$

- The total time complexity of phase 2 is then  $O(n^2)$ . Thus, the time complexity of the algorithm is  $O(n^2)$ .

# Insertion Sort

- Insertion sort is the sort that results when we perform a PriorityQueueSort implementing the priority queue with a sorted sequence.
- We improve phase 2 to  $O(n)$ .
- However, phase 1 now becomes the bottleneck for the running time. The first `insertItem` takes  $O(1)$ , the second  $O(2)$ , until the last operation takes  $O(n)$ .
- The run time of phase 1 is  $O(n^2)$  thus the run time of the algorithm is  $O(n^2)$ .

# Insertion Sort(cont.)

	Sequence $S$	Priority Queue $P$
Input	(7, 4, 8, 2, 5, 3, 9)	()
Phase 1:		
(a)	(4, 8, 2, 5, 3, 9)	(7)
(b)	(8, 2, 5, 3, 9)	(4, 7)
(c)	(2, 5, 3, 9)	(4, 7, 8)
(d)	(5, 3, 9)	(2, 4, 7, 8)
(e)	(3, 9)	(2, 4, 5, 7, 8)
(f)	(9)	(2, 3, 4, 5, 7, 8)
(g)	()	(2, 3, 4, 5, 7, 8, 9)
Phase 2:		
(a)	(2)	(3, 4, 5, 7, 8, 9)
(b)	(2, 3)	(4, 5, 7, 8, 9)
...	...	...
(g)	(2, 3, 4, 5, 7, 8, 9)	()

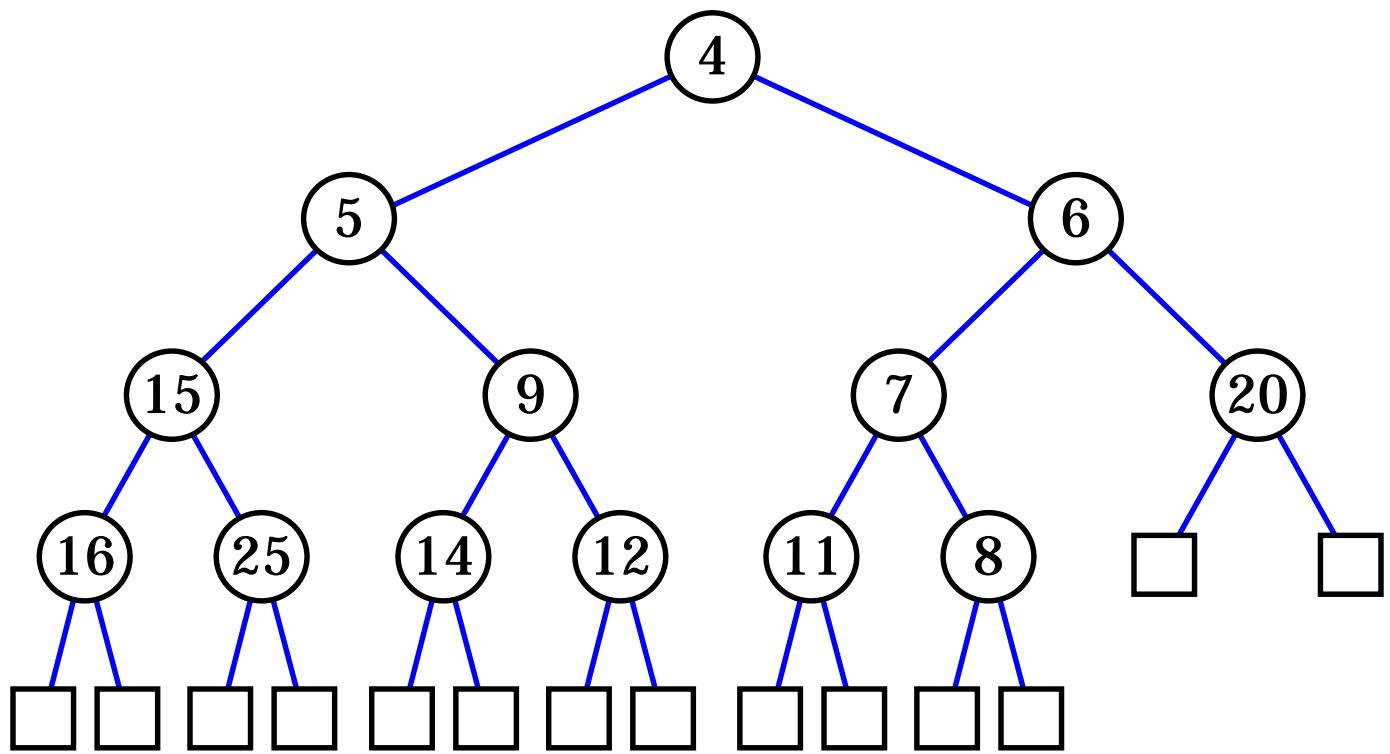

- Selection and insertion sort both take  $O(n^2)$ .
- Selection sort will always take  $\Omega(n^2)$  time, no matter the input sequence.
- The run of insertion sort varies depends on the input sequence.
- We have yet to see the ultimate priority queue....

# Heaps

- A **Heap** is a Binary Tree  $H$  that stores a collection of keys at its internal nodes and that satisfies two additional properties:
  - 1) **Heap-Order Property**
  - 2) **Complete Binary Tree Property**
- **Heap-Order Property** (**Relational**): In a heap  $H$ , for every node  $v$  (except the root), the key stored in  $v$  is greater than or equal to the key stored in  $v$ 's parent.
- **Complete Binary Tree Property** (**Structural**): A Binary Tree  $T$  is complete if each level but the last is full, and, in the last level, all of the internal nodes are to the left of the external nodes.

# Heaps (contd.)

- An Example:

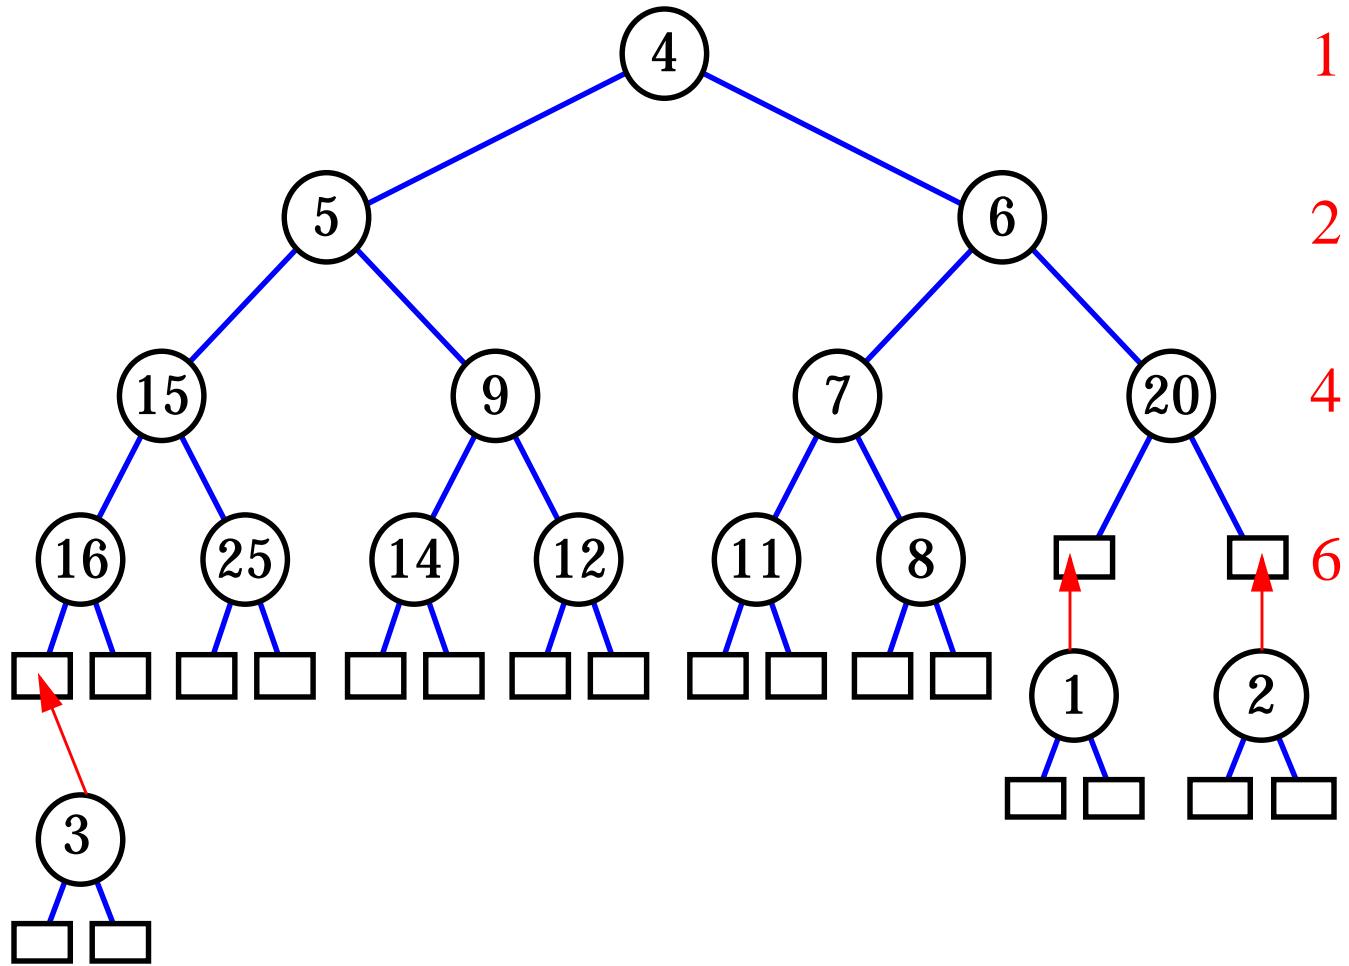

# Height of a Heap

- **Proposition:** A heap  $H$  storing  $n$  keys has height  $h = \lceil \log(n+1) \rceil$
- Justification: Due to  $H$  being complete, we know:
  - # of internal nodes is at least :  
$$1 + 2 + 4 + \dots + 2^{h-2} + 1 = 2^{h-1} - 1 + 1 = 2^{h-1}$$
  - # of internal nodes is at most:  
$$1 + 2 + 4 + \dots + 2^{h-1} = 2^h - 1$$
  - Therefore:  
$$2^{h-1} \leq n \text{ and } n \leq 2^h - 1$$
  - Which implies that:  
$$\log(n + 1) \leq h \leq \log n + 1$$
  - Which in turn implies:  
$$h = \lceil \log(n+1) \rceil$$
  - Q.E.D.

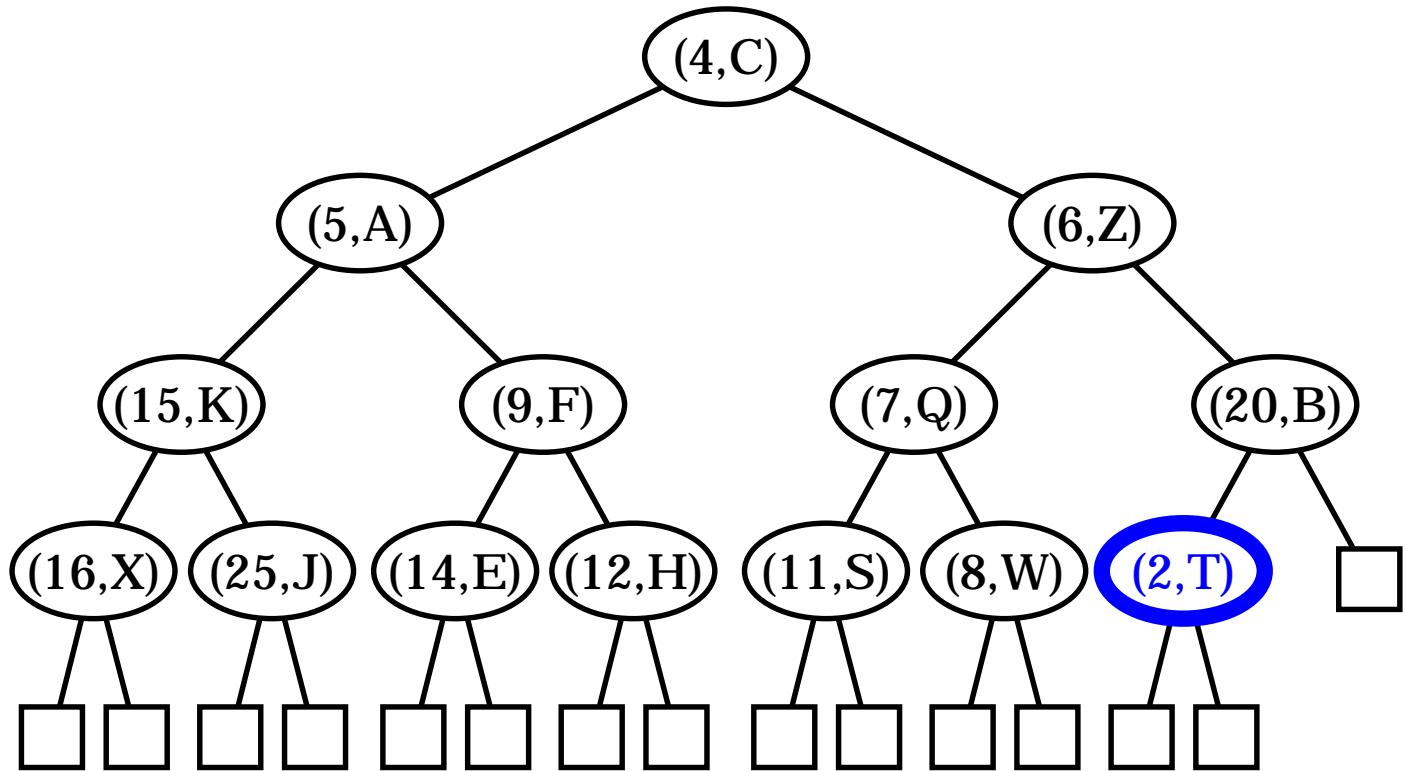

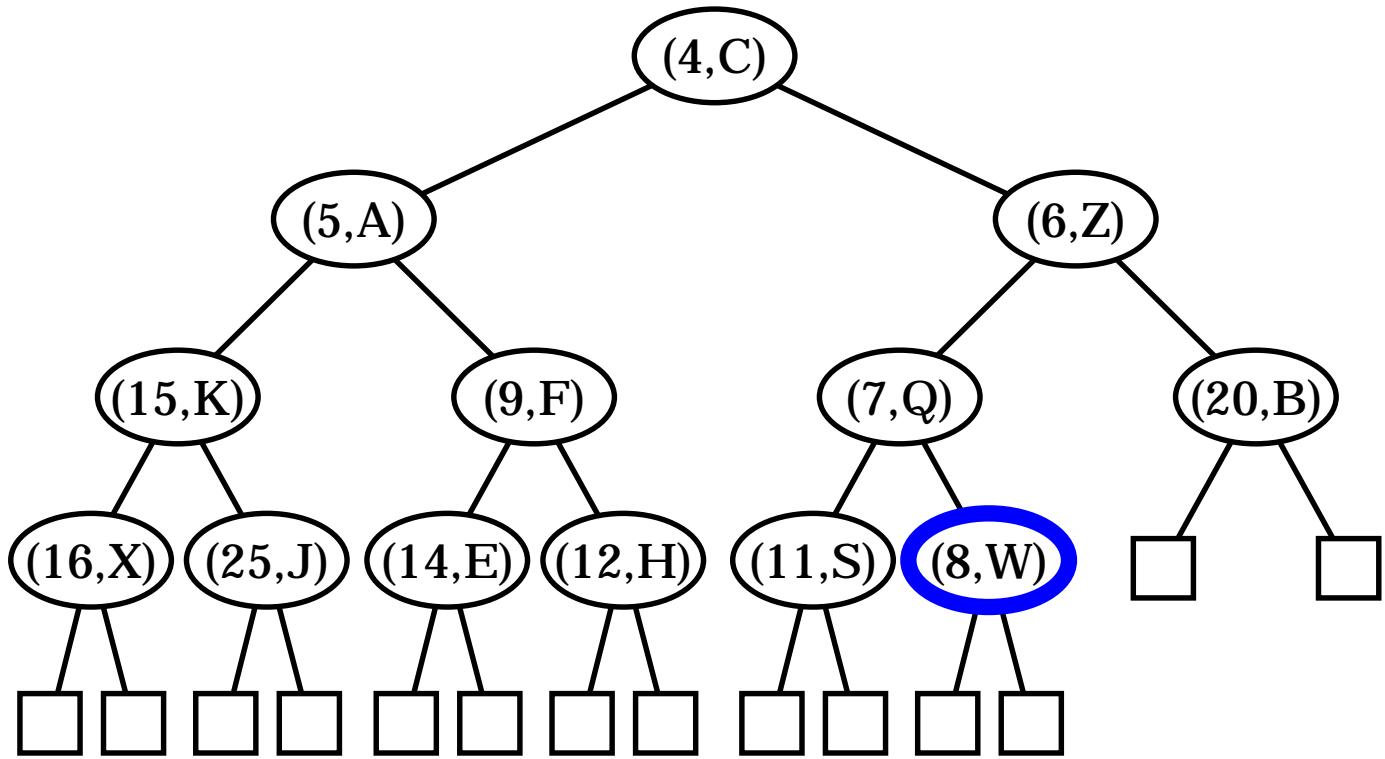

# Heigh of a Heap (contd.)

- Let's look at that graphically:

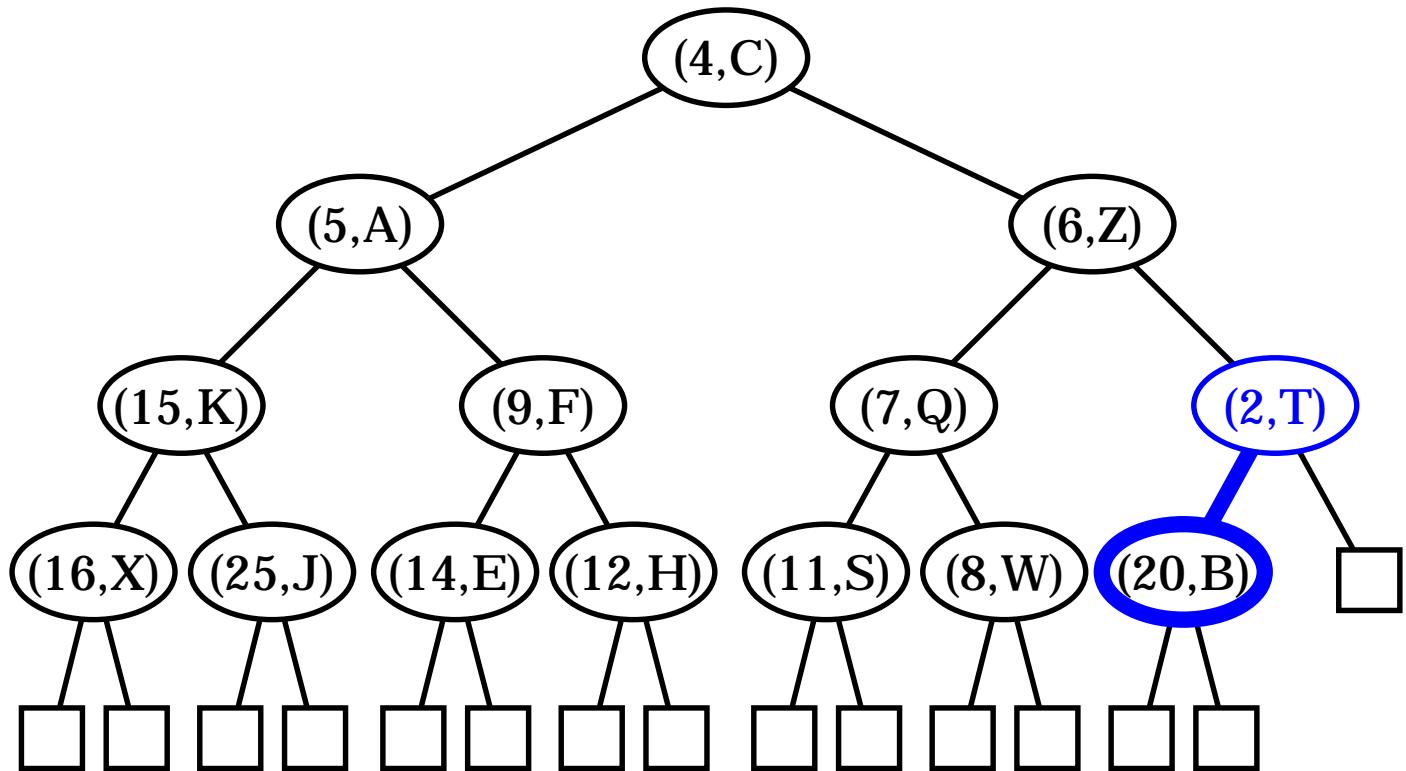

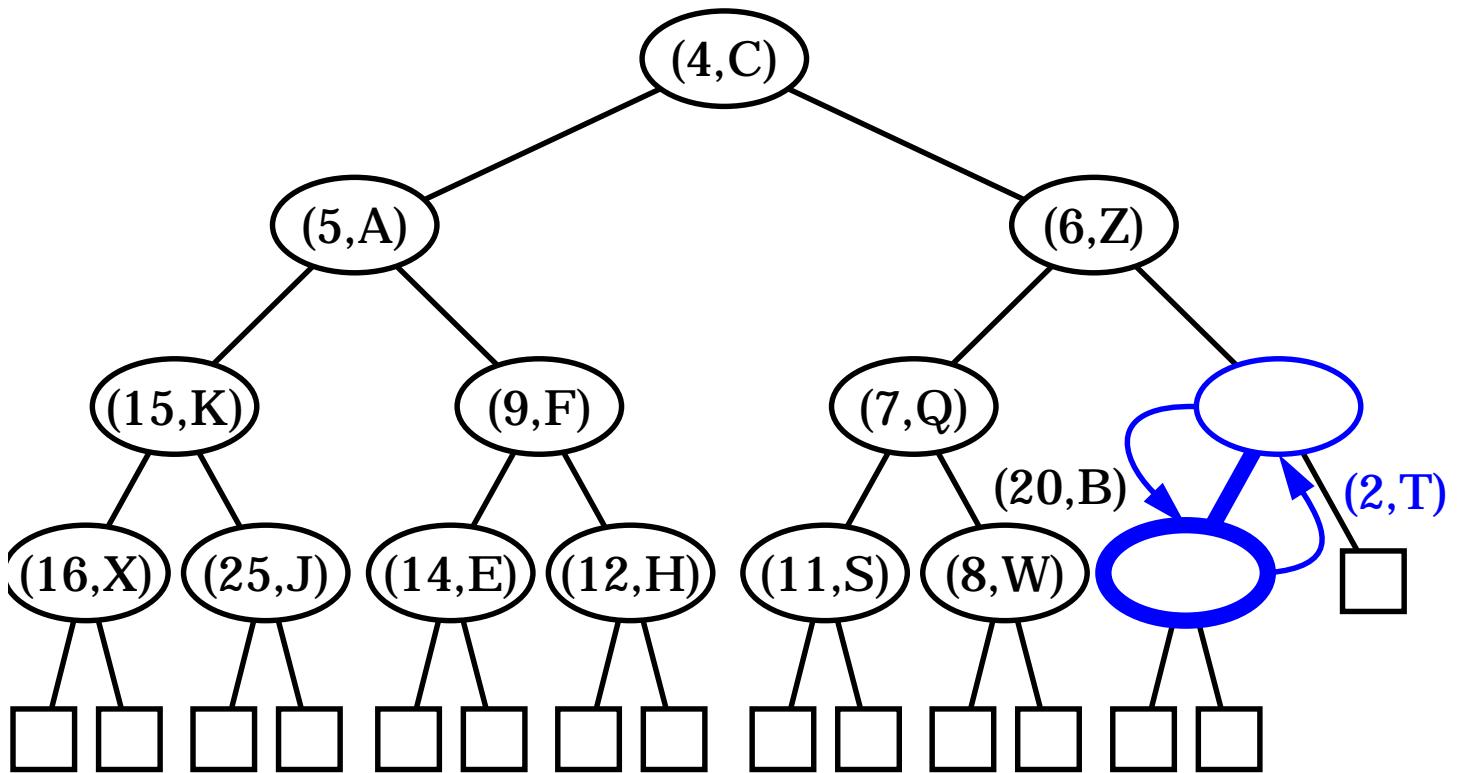

- Consider this heap which has height  $h = 4$  and  $n = 13$
- Suppose two more nodes are added. To maintain completeness of the tree, the two external nodes in level 4 will become internal nodes: i.e.  
 $n = 15, h = 4 = \log(15+1)$
- Add one more:  $n = 16, h = 5 = \lceil \log(16+1) \rceil$

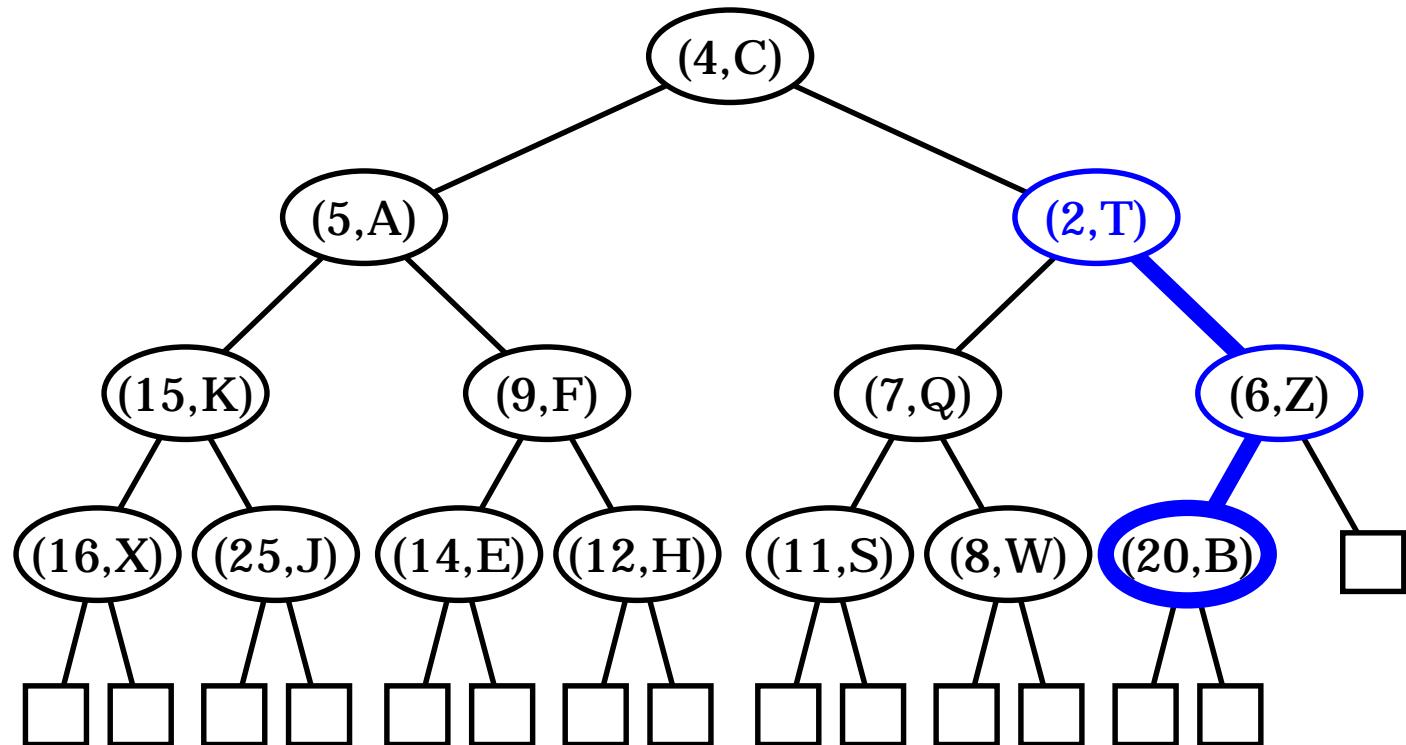

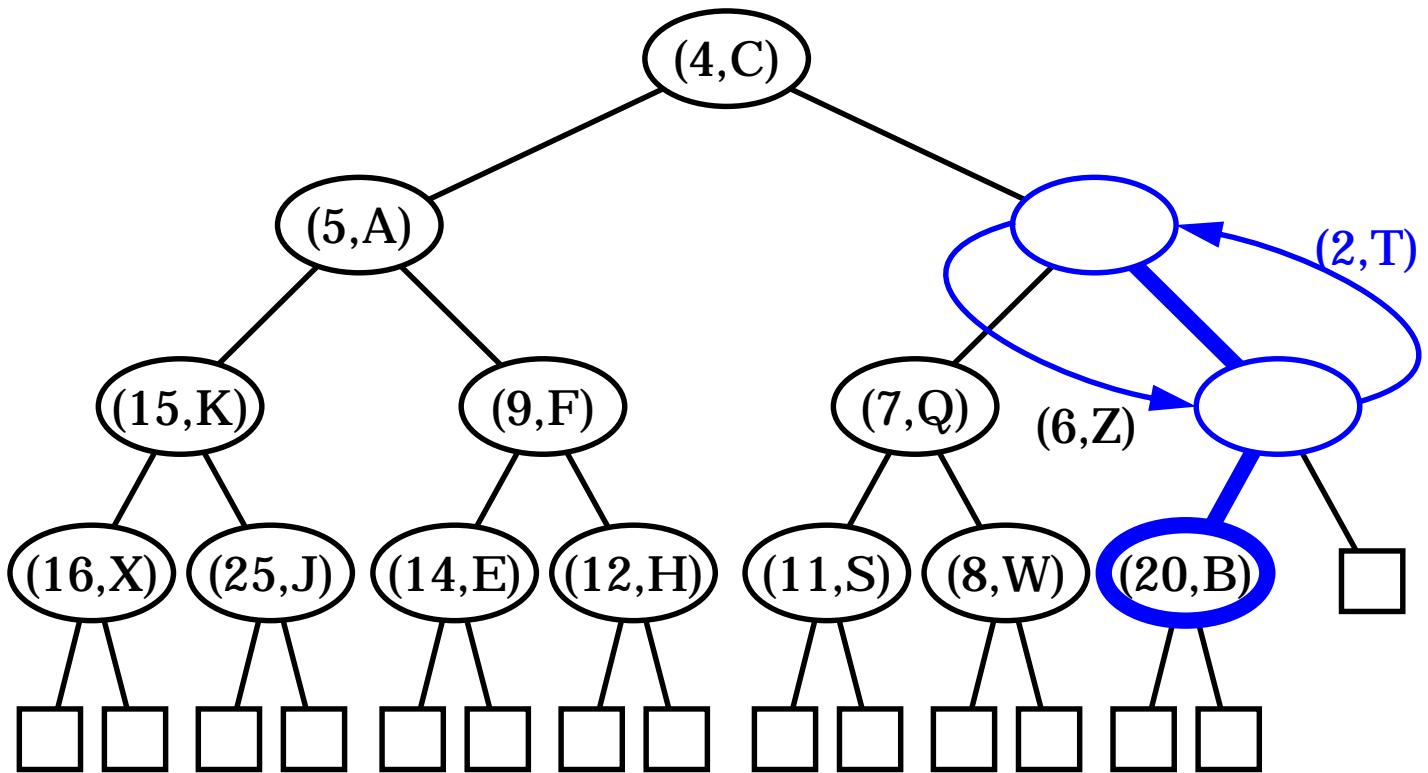

# Insertion into a Heap

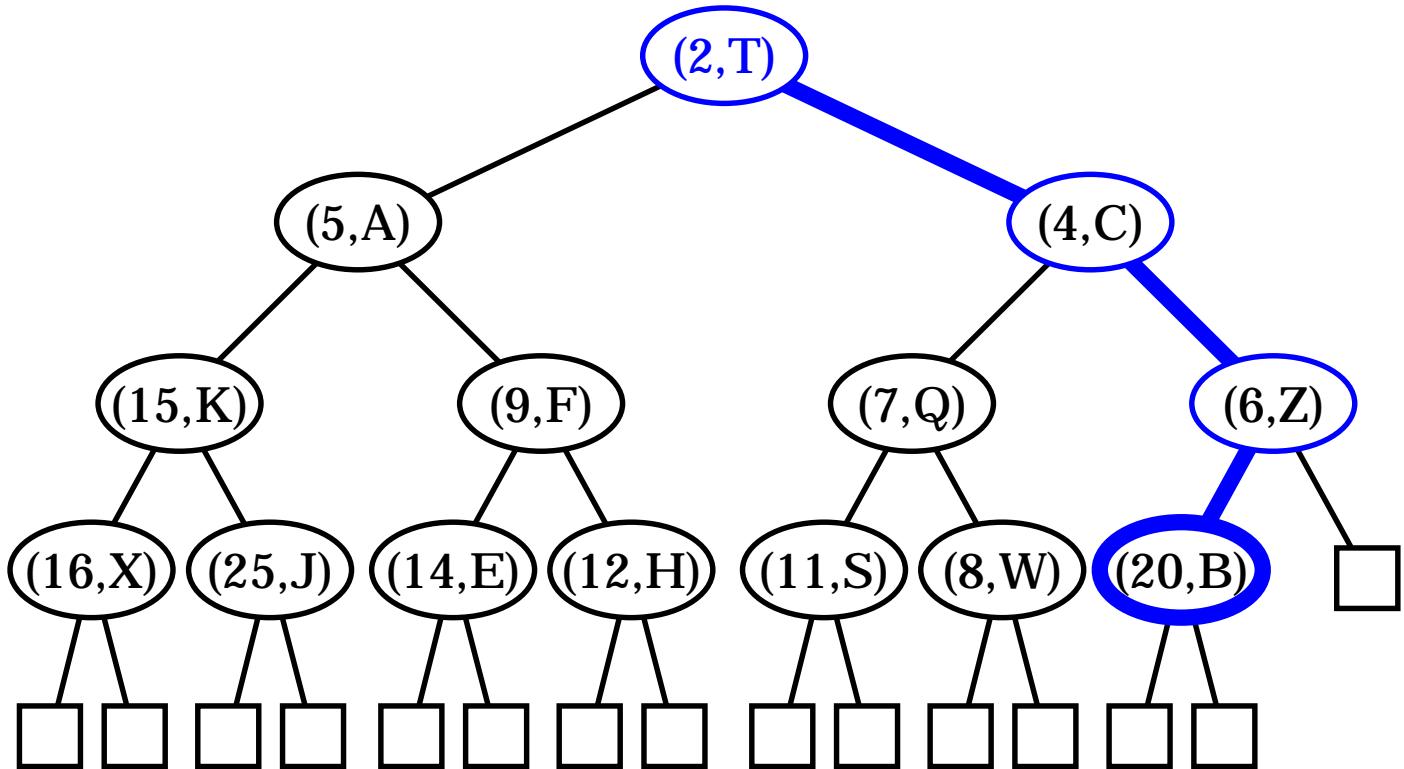

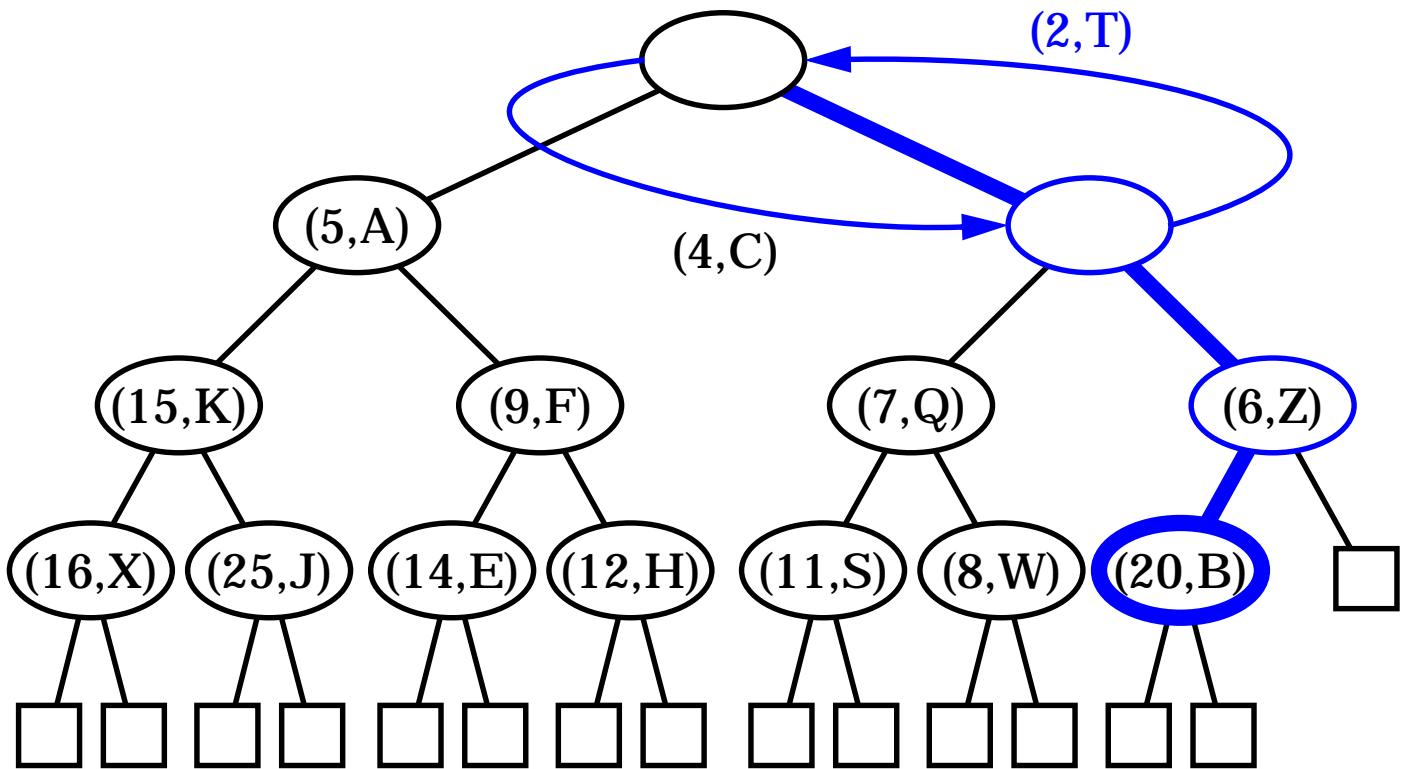

# Insertion into a Heap (cont.)

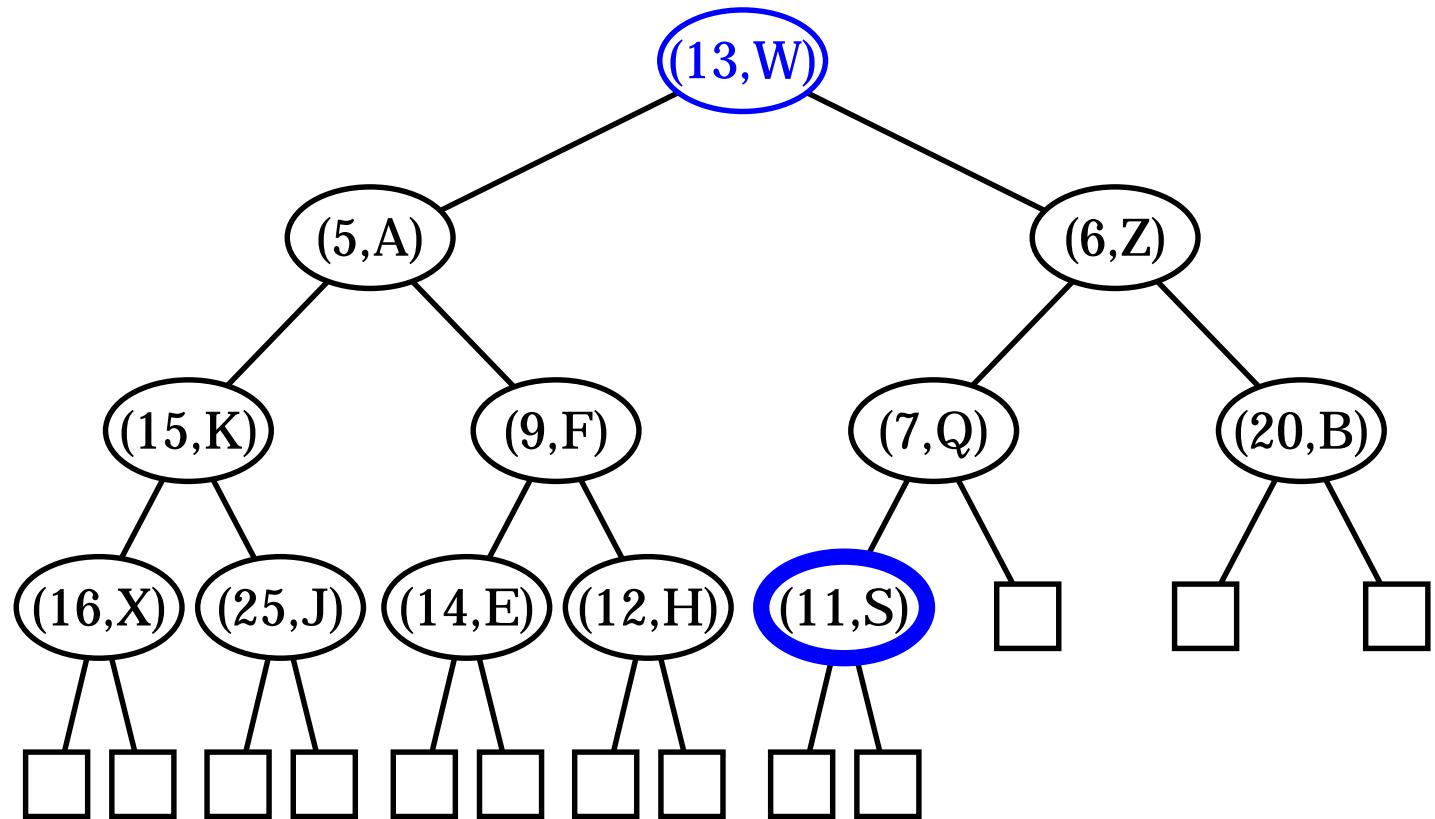

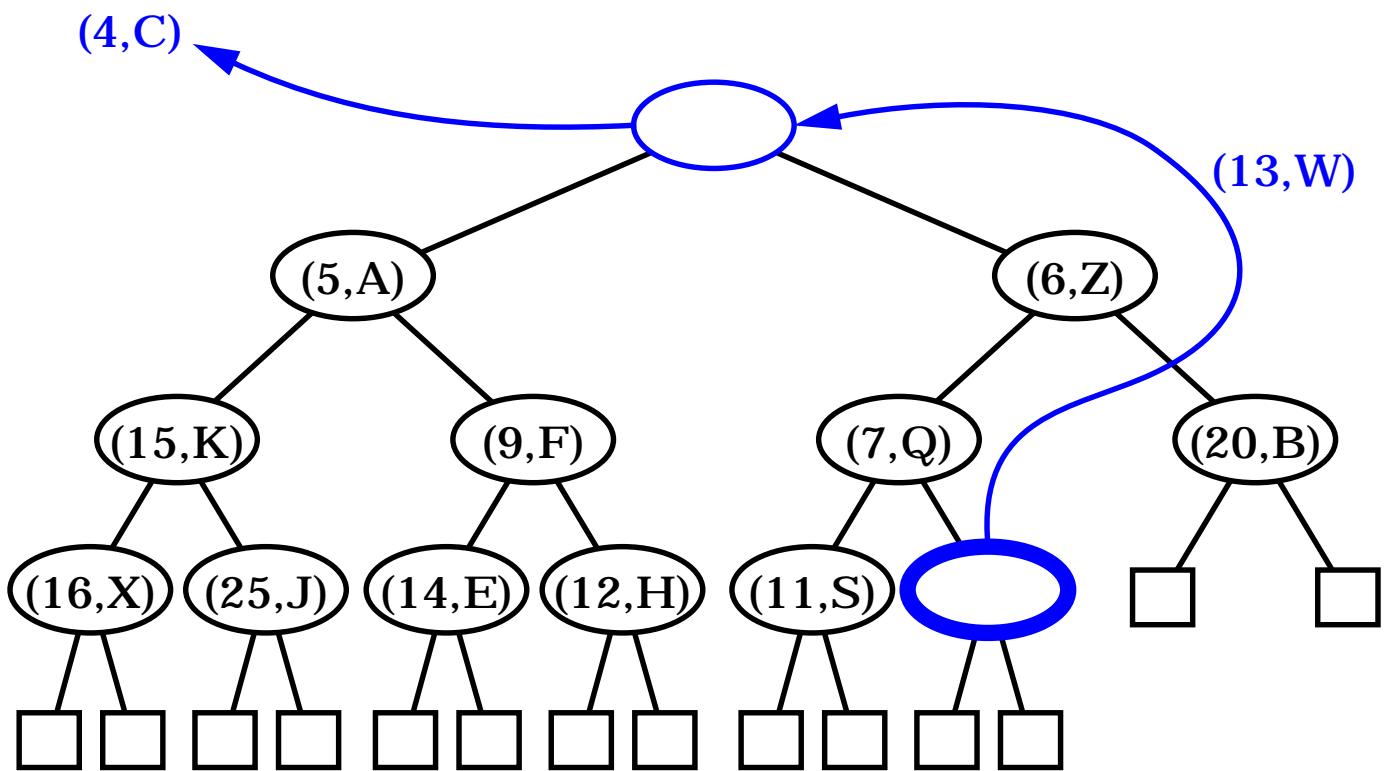

# Insertion into a Heap (cont.)

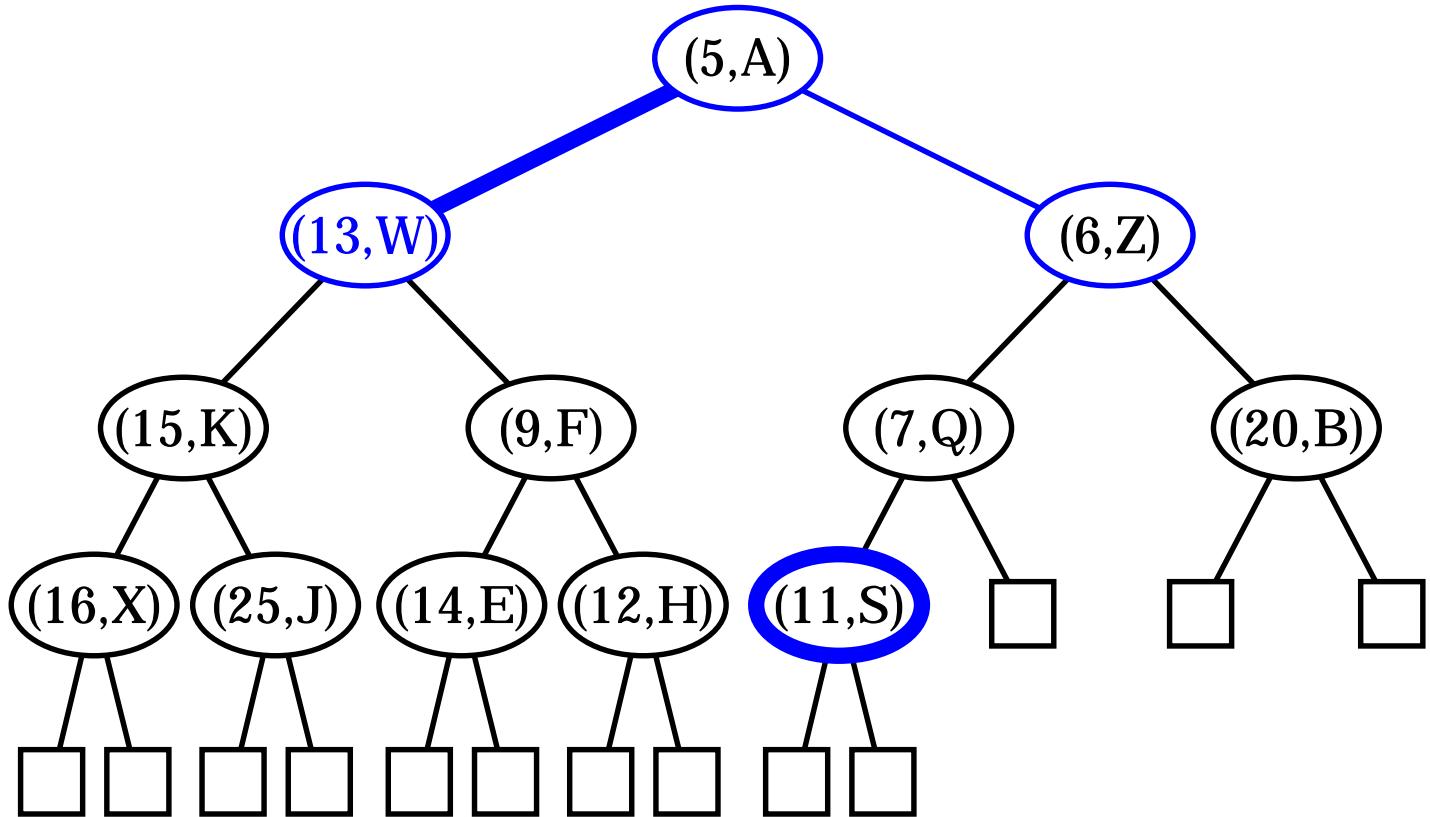

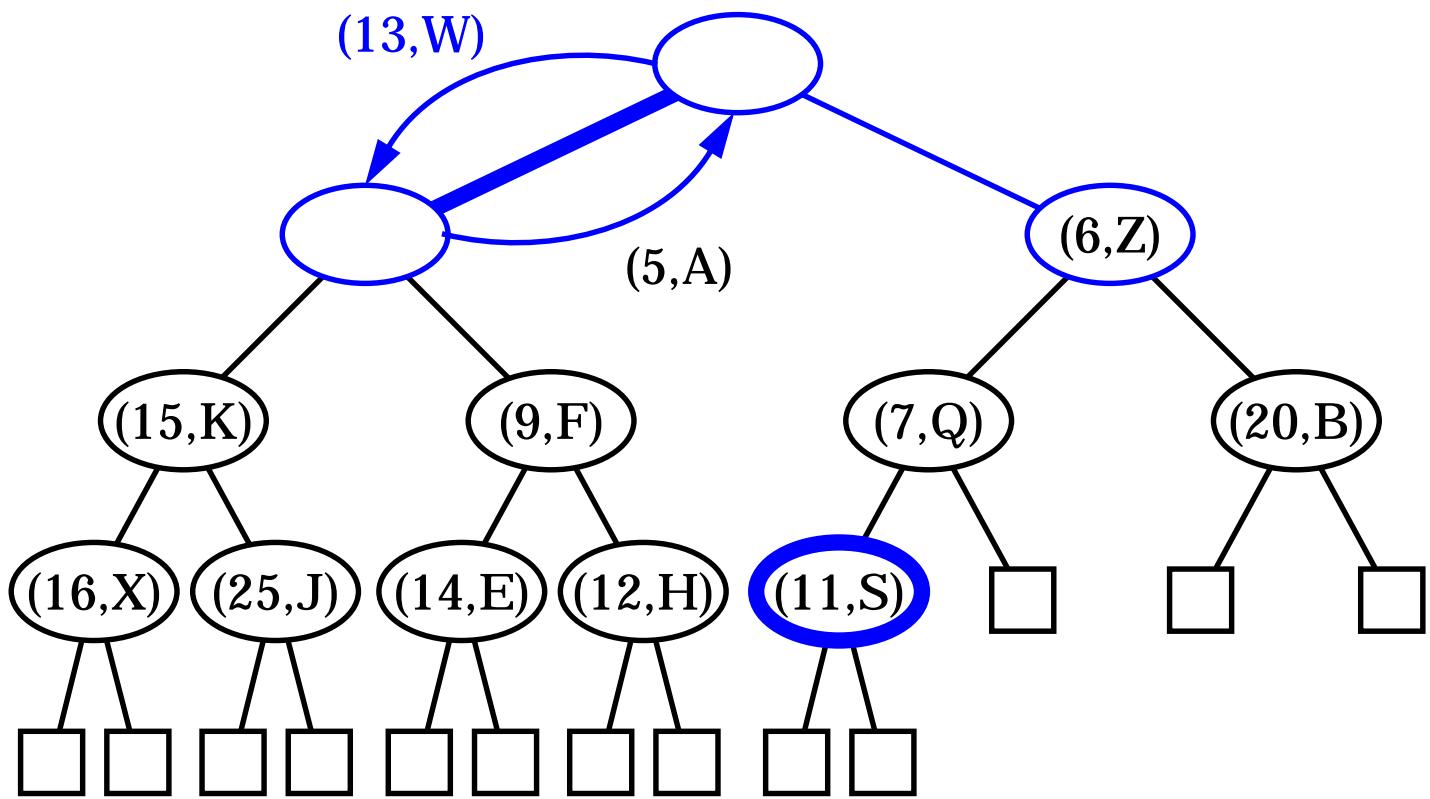

# Insertion into a Heap (cont.)

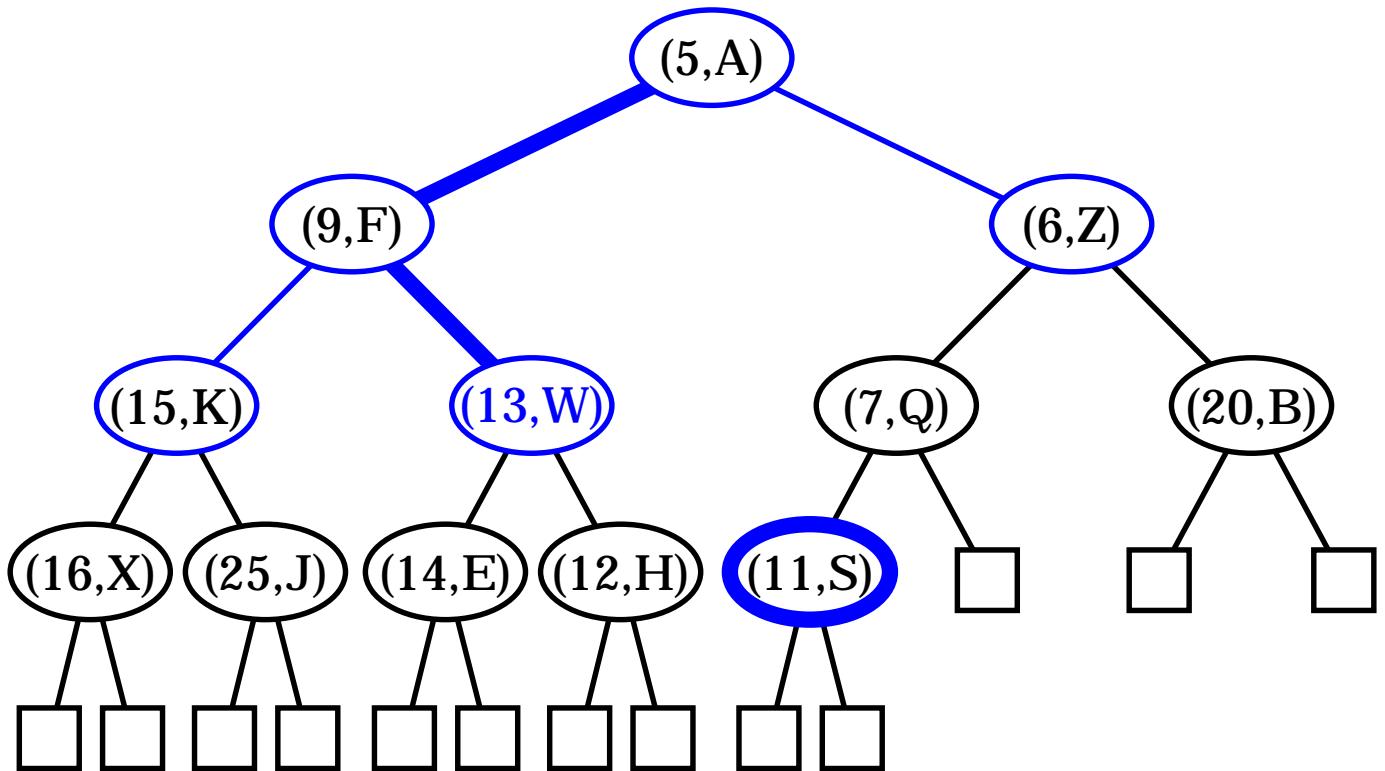

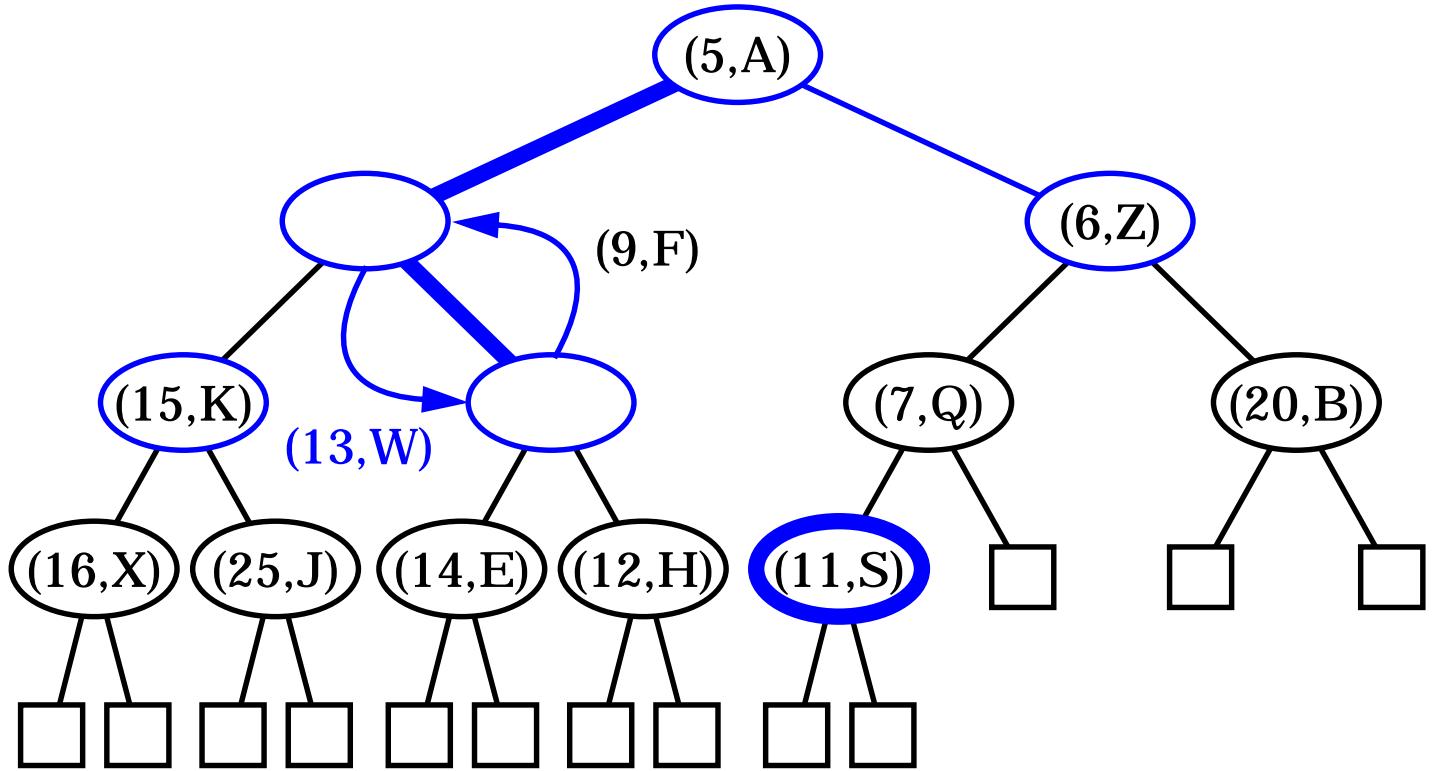

# Removal from a Heap

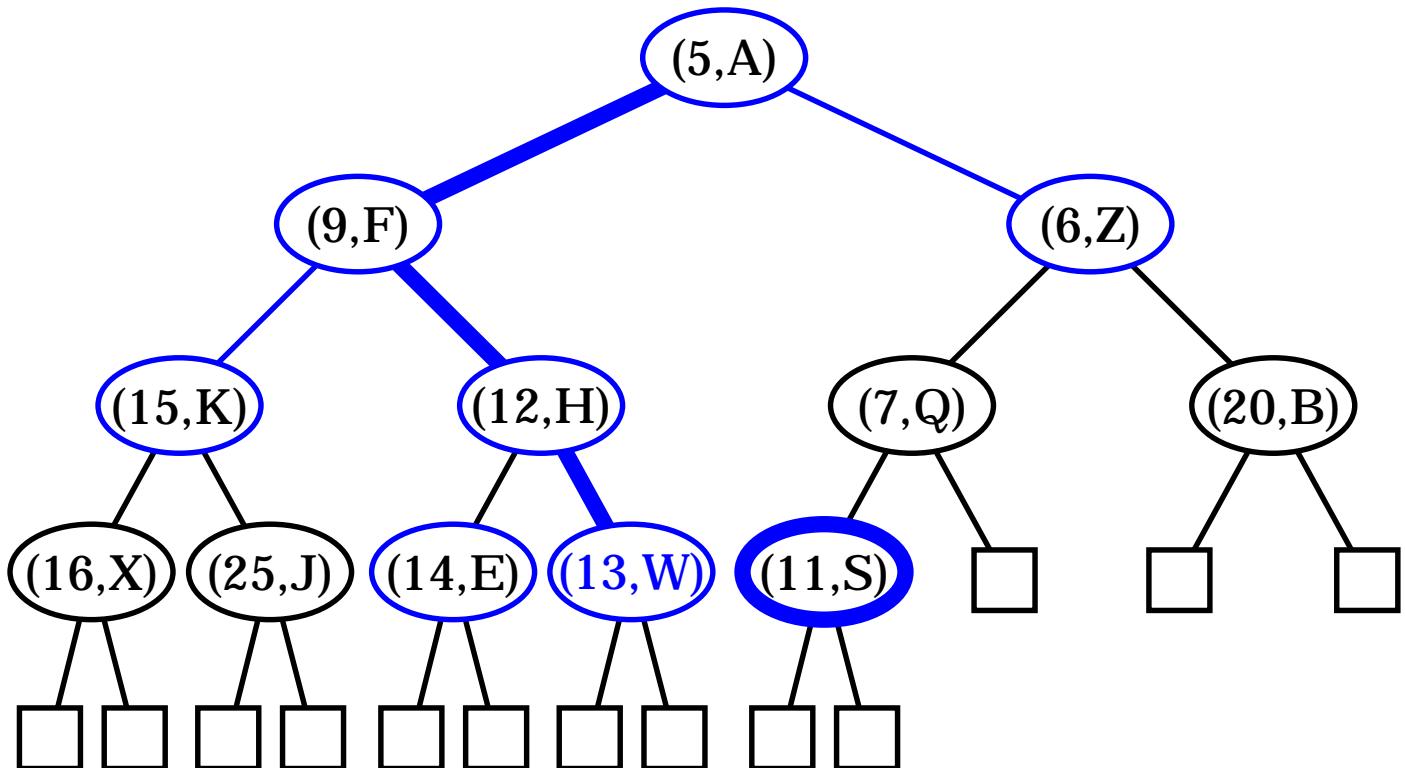

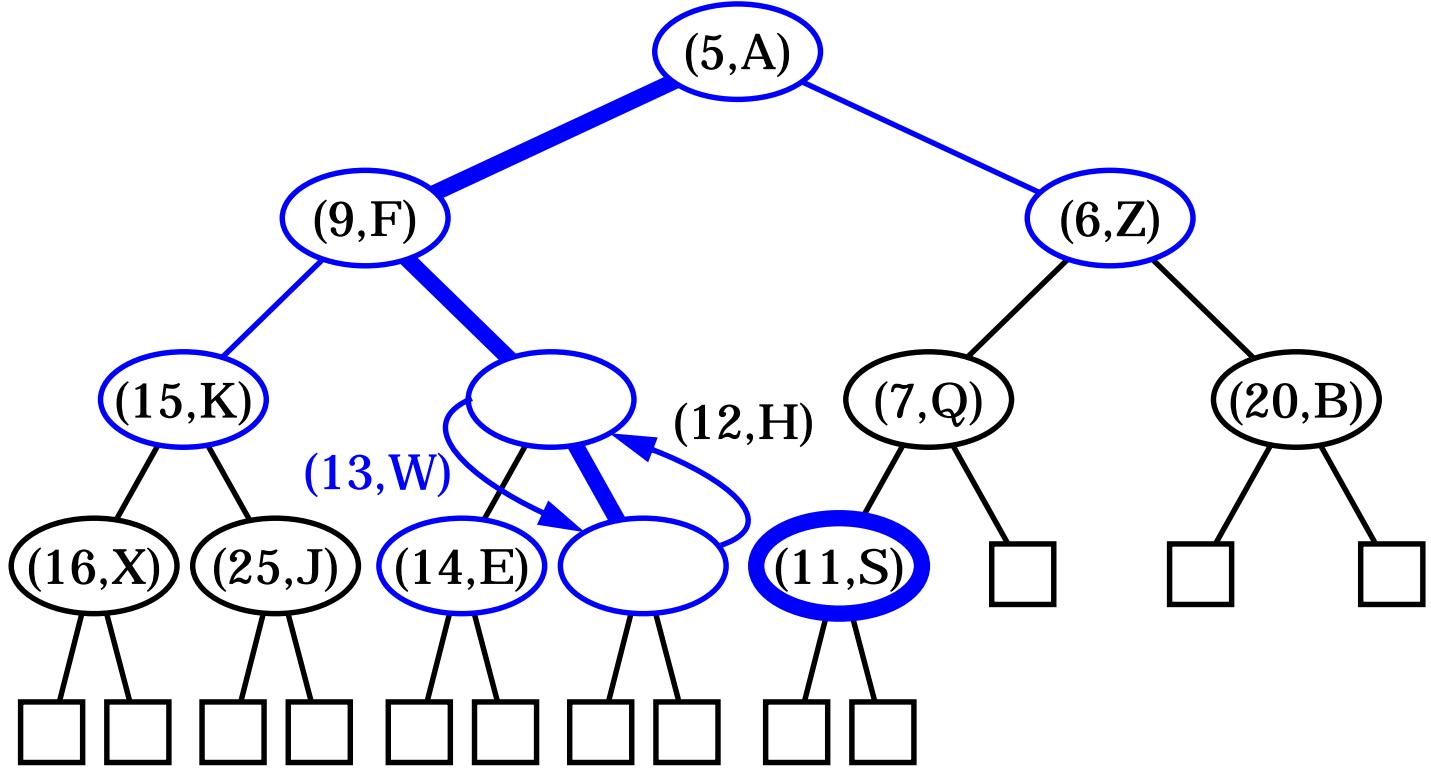

# Removal from a Heap (cont.)

# Removal from a Heap (cont.)

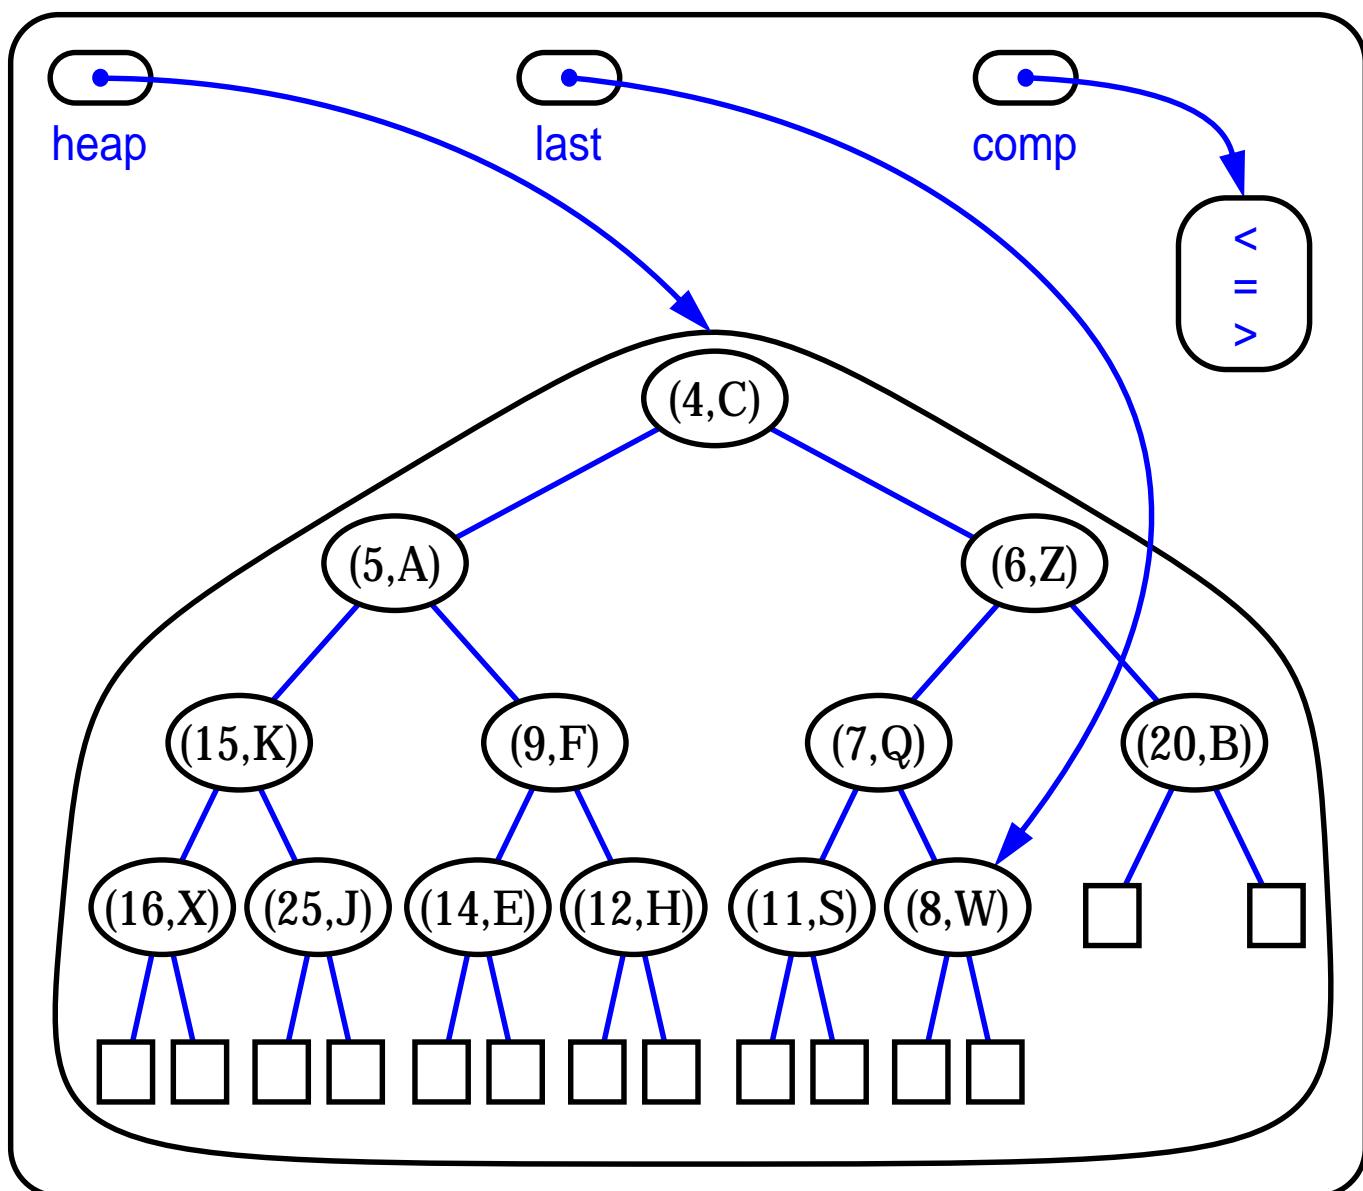

# Removal from a Heap(cont.)

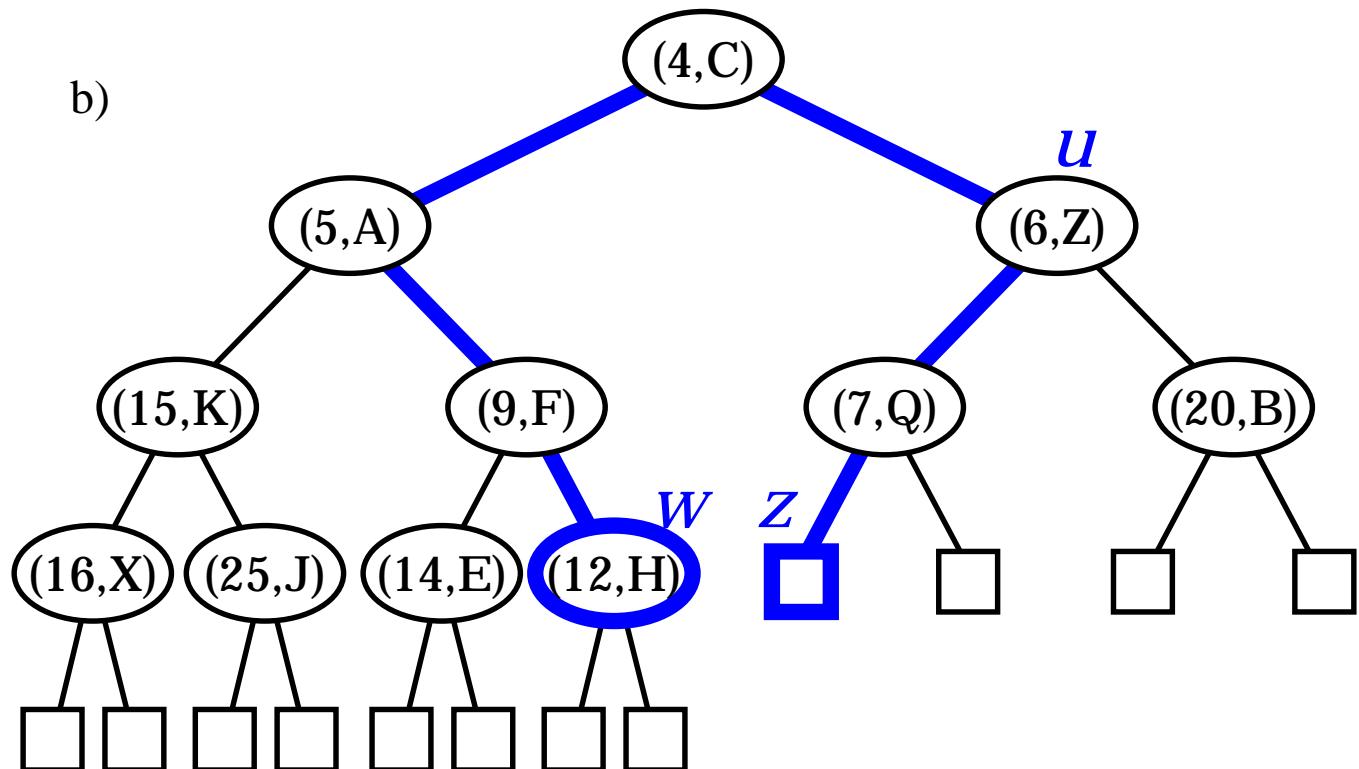

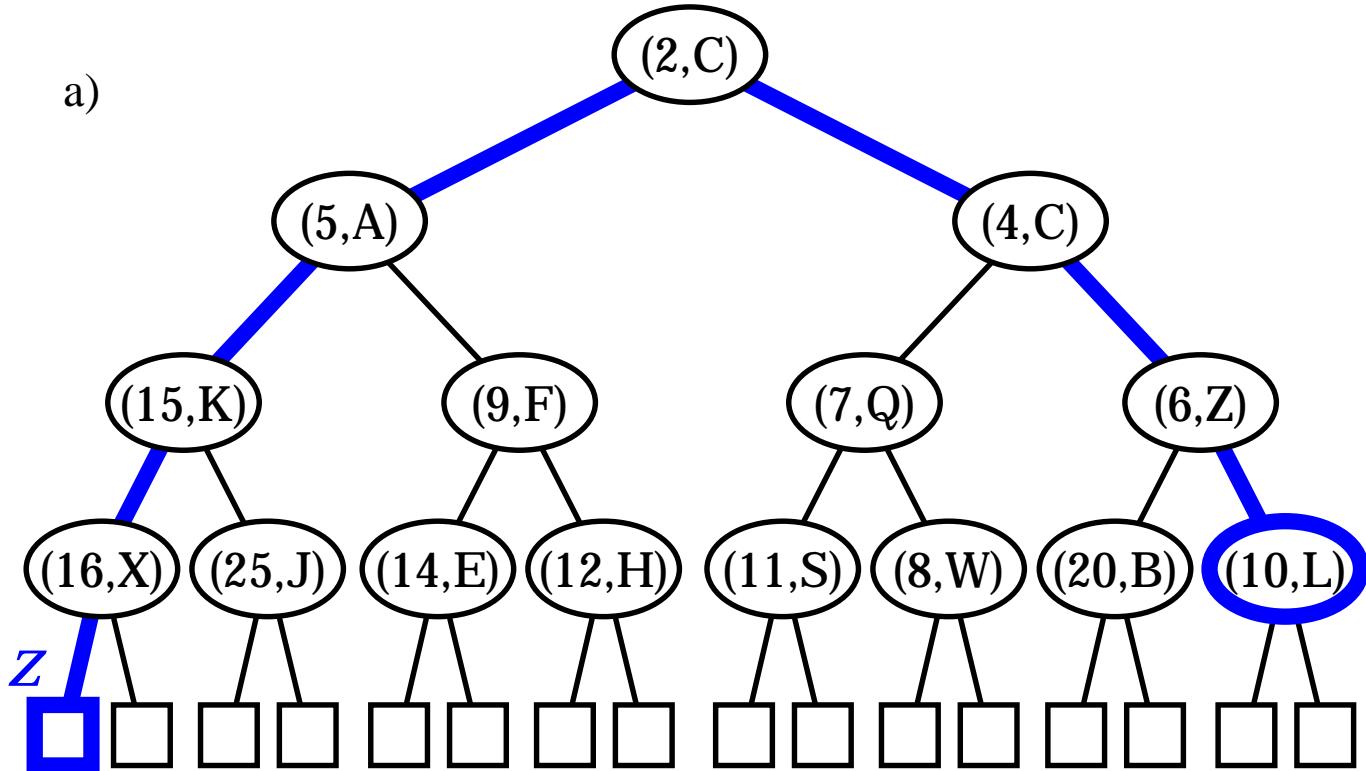

# Implementation of a Heap

```
public class HeapSimplePriorityQueue implements  
    SimplePriorityQueue {  
  
    BinaryTree T;  
  
    Position last;  
  
    Comparator comparator;  
  
    ...  
}
```

# Implementation of a Heap(cont.)

- Two ways to find the insertion position z in a heap:

# Heap Sort

- All heap methods run in logarithmic time or better
- If we implement PriorityQueueSort using a heap for our priority queue, `insertItem` and `removeMinElement` each take  $O(\log k)$ ,  $k$  being the number of elements in the heap at a given time.
- We always have  $n$  or less elements in the heap, so the worst case time complexity of these methods is  $O(\log n)$ .
- Thus each phase takes  $O(n \log n)$  time, so the algorithm runs in  $O(n \log n)$  time also.
- This sort is known as **heap-sort**.
- The  $O(n \log n)$  run time of heap-sort is much better than the  $O(n^2)$  run time of selection and insertion sort.

# Bottom-Up Heap Construction

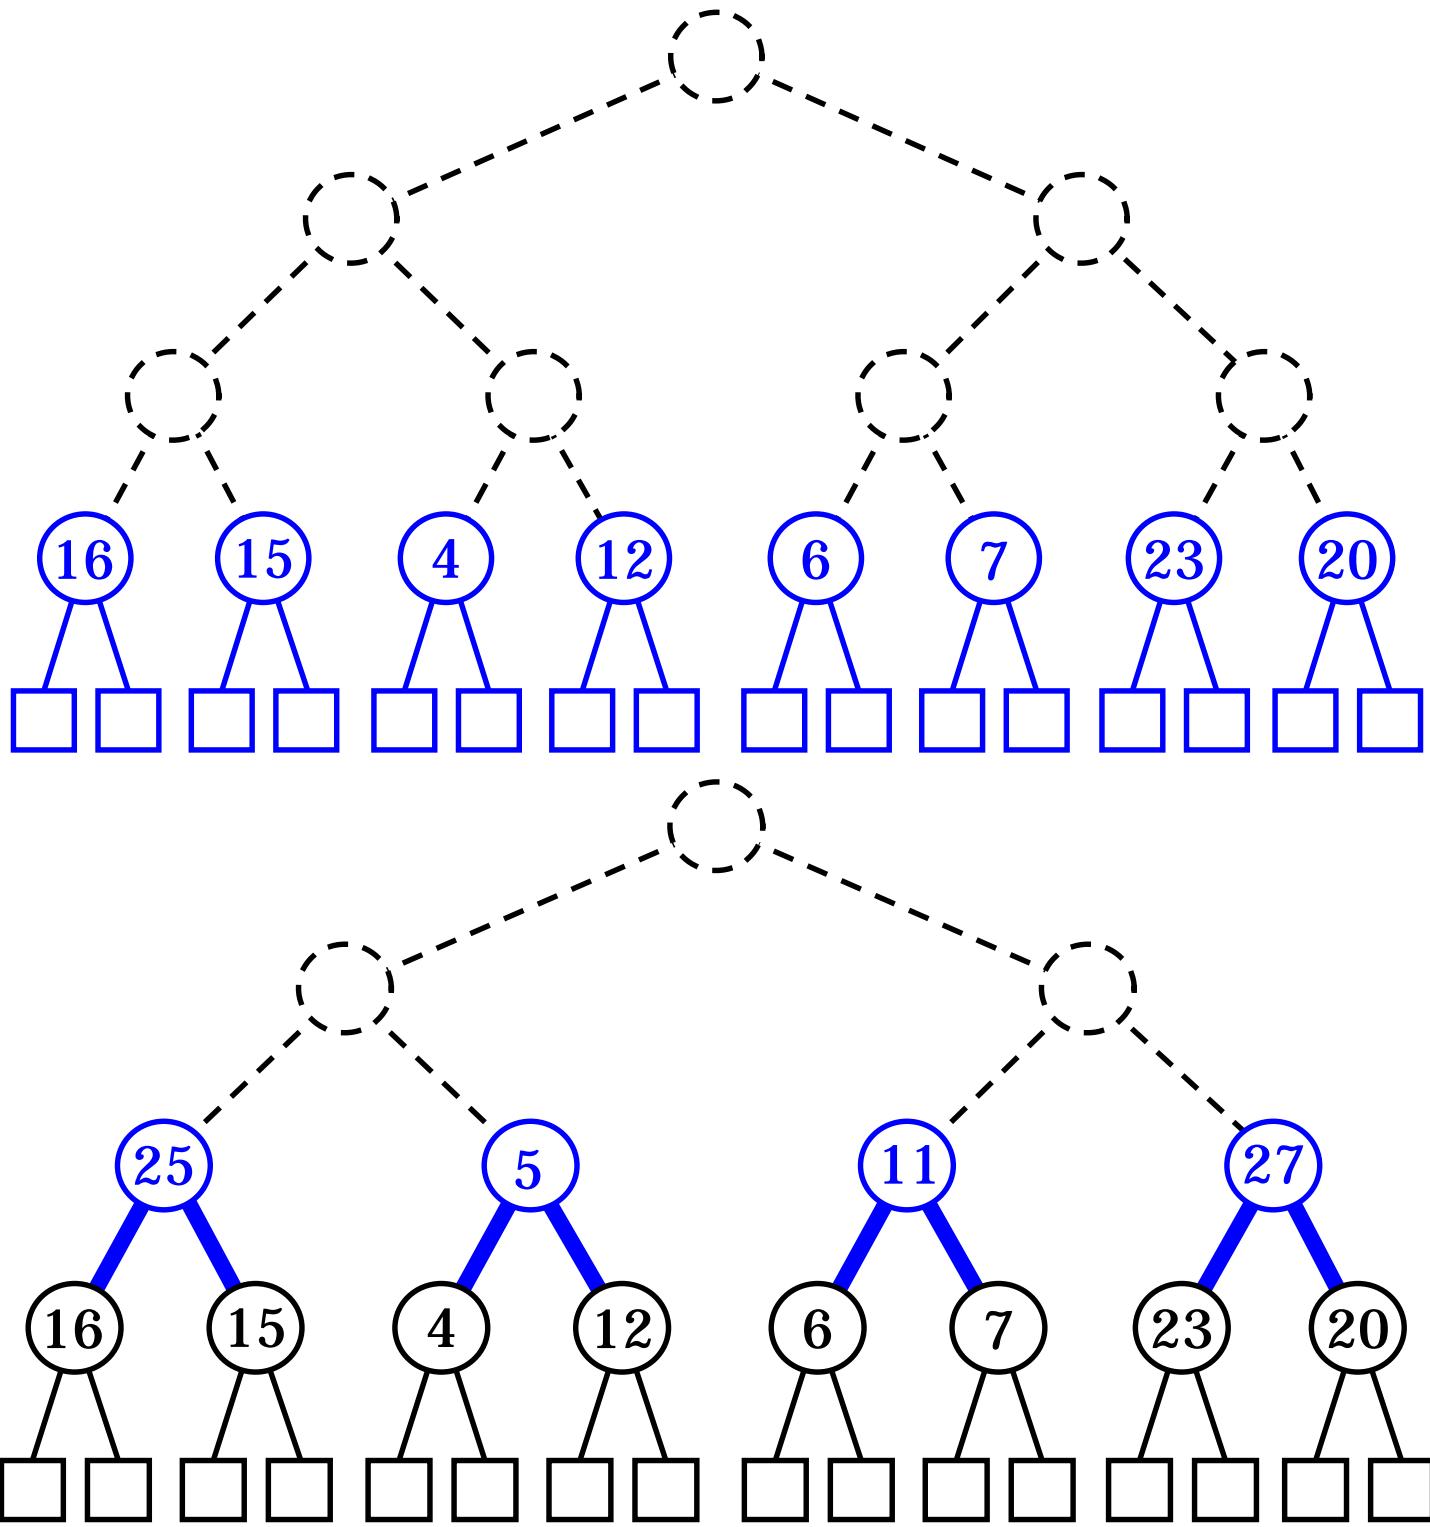

- If all the keys to be stored are given in advance we can build a heap **bottom-up** in  $O(n)$  time.
- Note: for simplicity, we describe bottom-up heap construction for the case for  $n$  keys where:

$$n = 2^h - 1$$

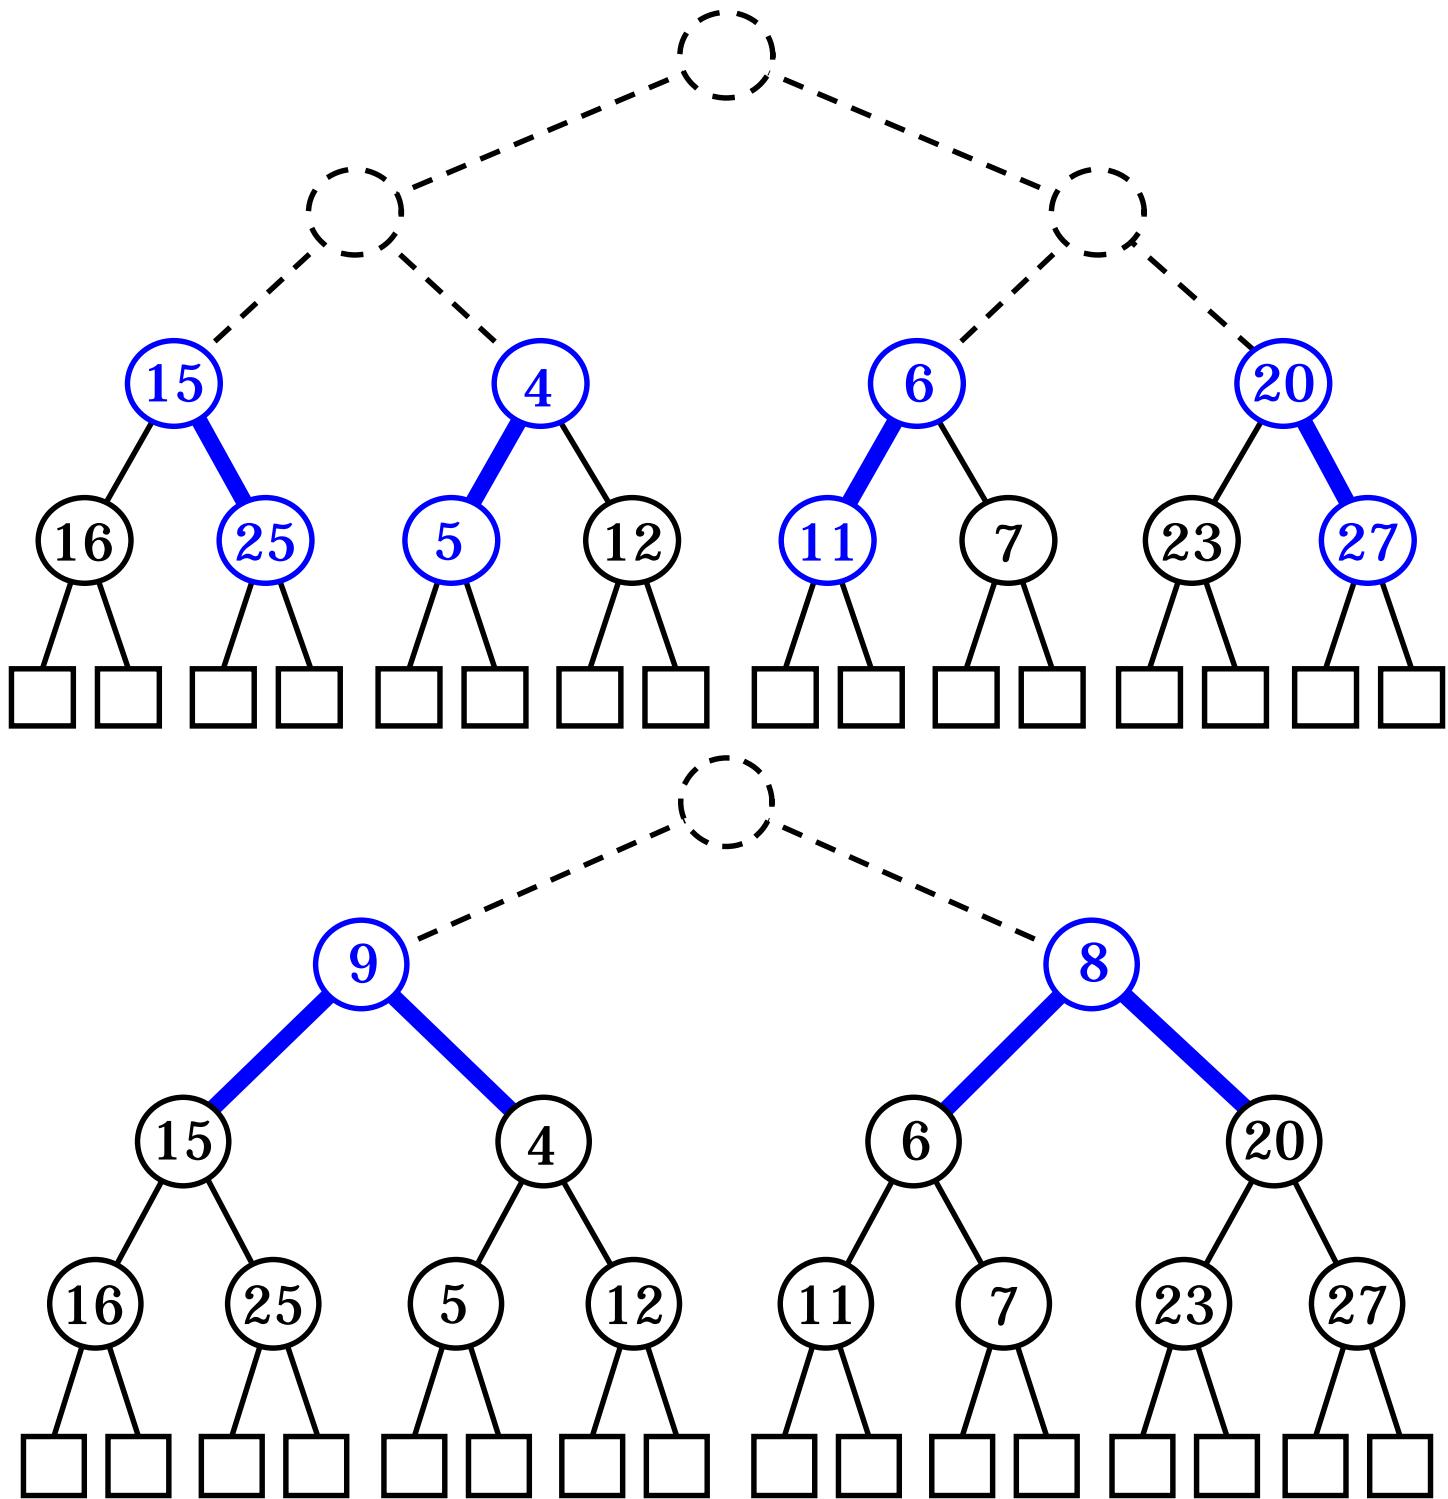

$h$  being the height.

- Steps:
  - 1) Construct  $(n+1)/2$  elementary heaps with one key each.
  - 2) Construct  $(n+1)/4$  heaps, each with 3 keys, by joining pairs of elementary heaps and adding a new key as the root. The new key may be swapped with a child in order to preserve heap-order property.
  - 3) Construct  $(n+1)/8$  heaps, each with 7 keys, by joining pairs of 3-key heaps and adding a new key. Again swaps may occur.
  - ...
  - 4) In the  $i$ th step,  $2 \leq i \leq h$ , we form  $(n+1)/2^i$  heaps, each storing  $2^i - 1$  keys, by joining pairs of heaps storing  $(2^{i-1} - 1)$  keys. Swaps may occur.

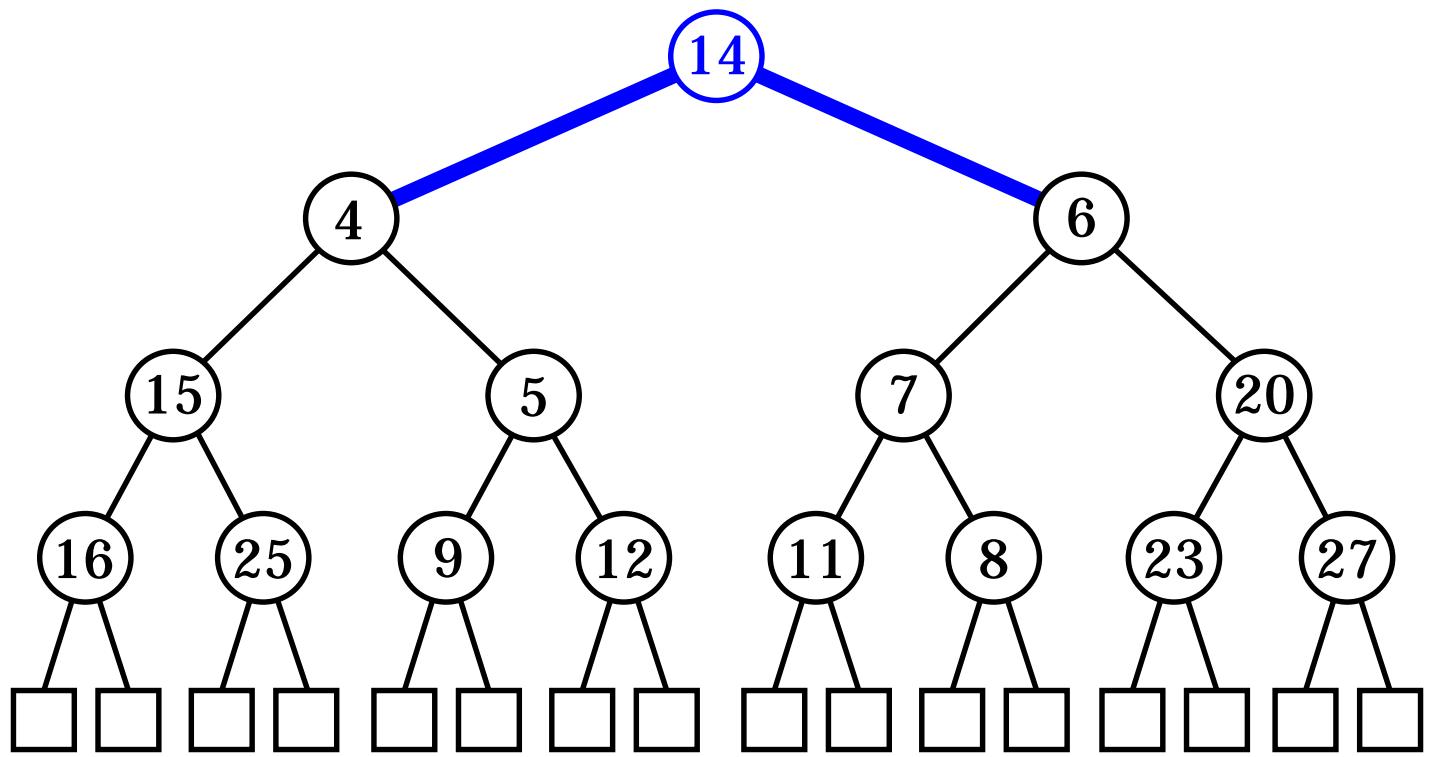

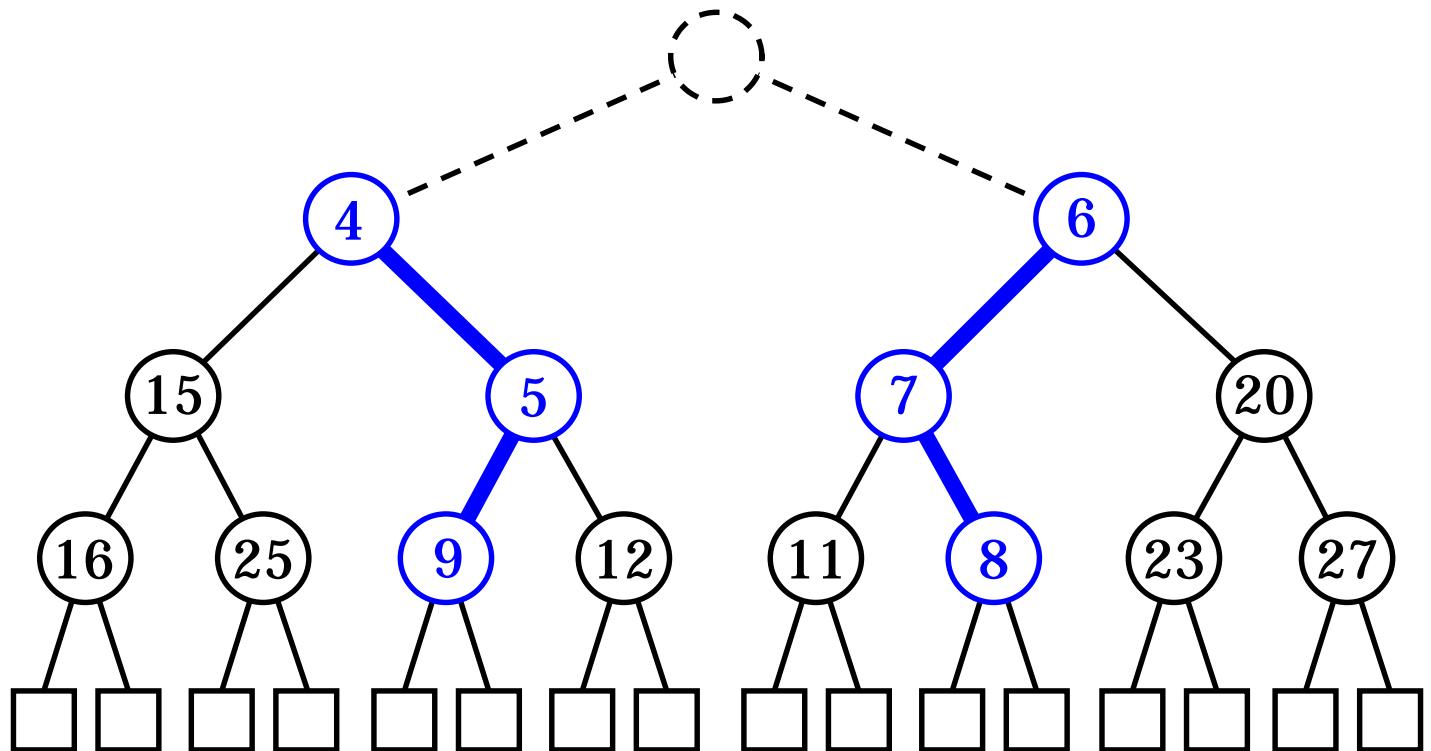

# Bottom-Up Heap Construction (cont.)

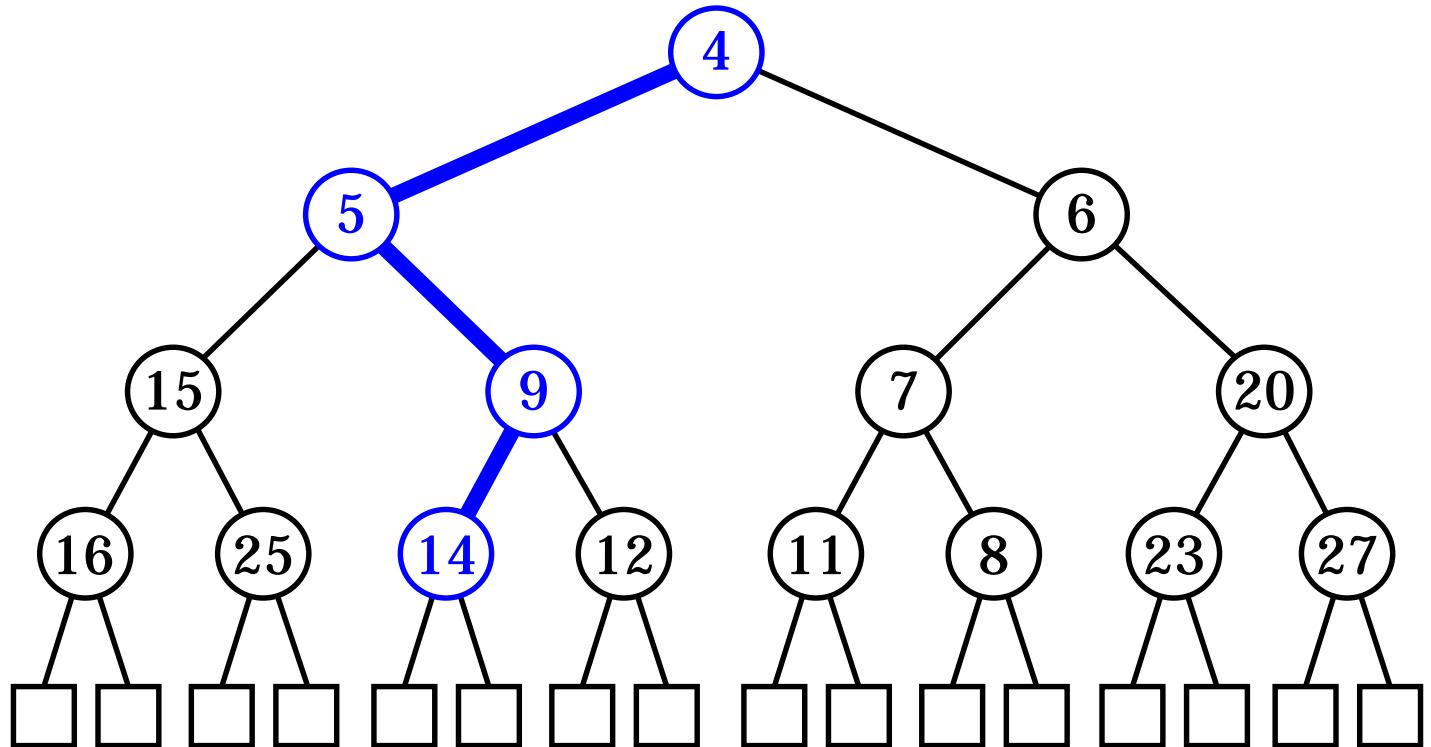

# Bottom-Up Heap Construction (cont.)

# Bottom-Up Heap Construction (cont.)

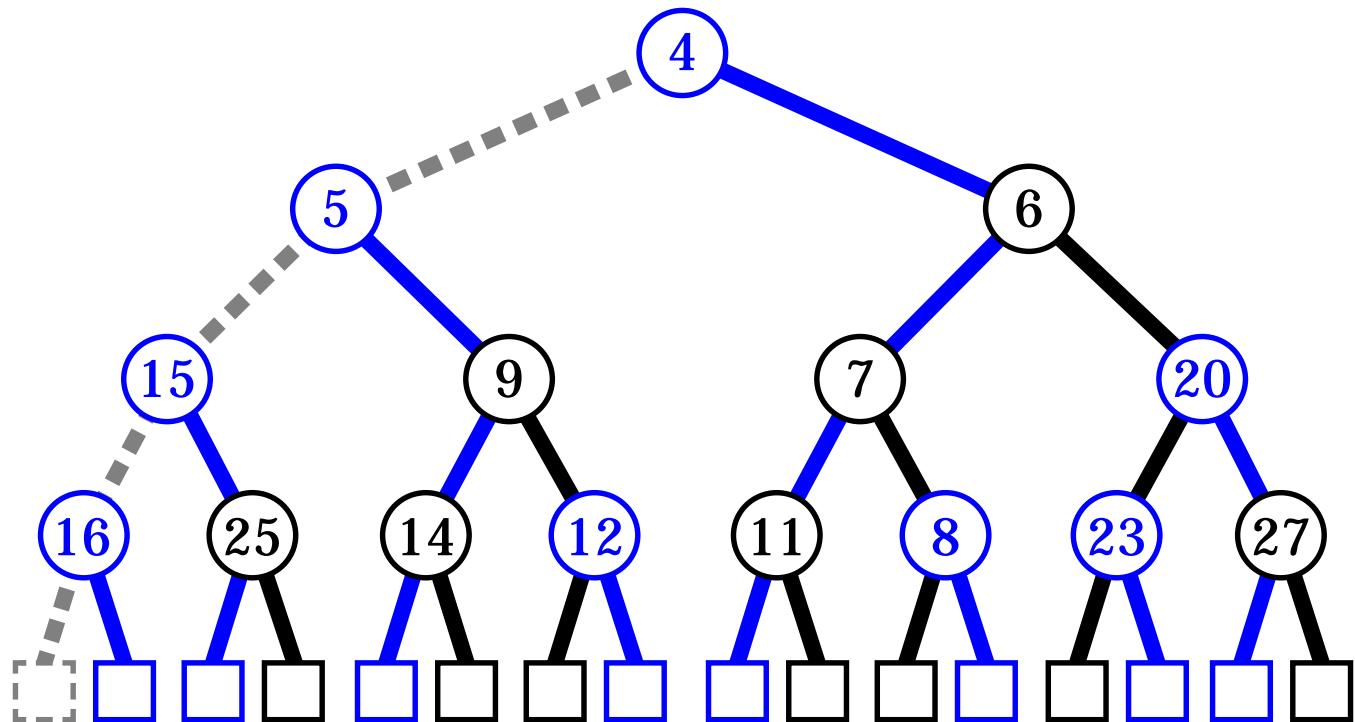

# Bottom-Up Heap Construction (cont.)

The End

# Analysis of Bottom-Up Heap Construction

- **Proposition:** Bottom-up heap construction with  $n$  keys takes  $O(n)$  time.
  - Insert  $(n + 1)/2$  nodes
  - Insert  $(n + 1)/4$  nodes
  - Upheap at most  $(n + 1)/4$  nodes 1 level.
  - Insert  $(n + 1)/8$  nodes
  - ...
  - Insert 1 node.
  - Upheap at most 1 node 1 level.

- $n$  inserts,  $n/2$  upheaps of 1 level =  $O(n)$

# Locators

- Locators can be used to keep track of elements in a container
- A locator sticks with a specific key-element pair, even if that element “moves around”.
- The Locator **ADT** supports the following fundamental methods:

**element():**      Return the element of the item associated with the Locator.

**Input:** None;    **Output:** Object

**key():**      Return the key of the item associated with the Locator.

**Input:** None;    **Output:** Object

**isContained():**      Return true if and only if the Locator is associated with a container.

**Input:** None;    **Output:** boolean

**container():**      Return the container associated with the Locator.

**Input:** None;    **Output:** boolean

# Priority Queue with Locators

- It is easy to extend the sequence-based and heap-based implementations of a Priority Queue to support Locators.
- The Priority Queue ADT can be extended to implement the Locator ADT
- In the heap implementation of a priority queue, we store in the locator object a key-element pair and a reference to its position in the heap.
- All of the methods of the Locator ADT can then be implemented in  $O(1)$  time.

# A Java Implementation of a Locator

```
public class LocItem extends Item implements Locator {
    private Container cont;
    private Position pos;
    LocItem (Object k, Object e, Position p, Container c) {
        super(k, e);
        pos = p;
        cont = c;
    }
    public boolean isContained() throws
        InvalidLocatorException {
        return cont != null;
    }
    public Container container() throws
        InvalidLocatorException { return cont; }
    protected Position position() {return pos; }
    protected void setPosition(Position p) { pos = p; }
    protected void setContainer(Container c) { cont = c; }
}
```

# A Java Implementation of a Locator-Based Priority Queue

```
public class SequenceLocPriorityQueue
    extends SequenceSimplePriorityQueue implements
PriorityQueue {
    //priority queue with locators implemented
    //with a sorted sequence
    public SequenceLocPriorityQueue (Comparator
comp) { super(comp); }
    // auxiliary methods
protected LocItem locRemove(Locator loc) {
    checkLocator(loc);
    seq.remove(((LocItem) loc).position());
    ((LocItem) loc).setContainer(null);
    return (LocItem) loc;
}
```

# Locator-Based PQ (contd.)

```
protected Locator locInsert(LocItem locit) throws  
InvalidKeyException {  
    Position p, curr;  
    Object k = locit.key();  
    if (!comp.isComparable(k))  
        throw new InvalidKeyException("The key is not valid");  
    else  
        if (seq.isEmpty())  
            p = seq.insertFirst(locit);  
        else if  
            (comp.isGreaterThan(k, extractKey(seq.last())))  
            p = seq.insertAfter(seq.last(), locit);  
        else {  
            curr = seq.first();  
            while (comp.isGreaterThan(k, extractKey(curr)))  
                curr = seq.after(curr);  
            p = seq.insertBefore(curr, locit);  
        }  
    locit.setPosition(p);  
    locit.setContainer(this);  
    return (Locator) locit;  
}
```

# Locator-Based PQ (contd.)

```
public void insert(Locator loc) throws  
InvalidKeyException {  
    locInsert((LocItem) loc);  
}  
  
public Locator insert(Object k, Object e) throws  
InvalidKeyException {  
    LocItem locit = new LocItem(k, e, null, null);  
    return locInsert(locit);  
}  
  
public void insertItem (Object k, Object e) throws  
InvalidKeyException {  
    insert(k, e);  
}  
  
public void remove(Locator loc) throws  
InvalidLocatorException {  
    locRemove(loc);  
}  
  
public Object removeMinElement () throws  
EmptyContainerException {  
    Object toReturn = minElement();  
    remove(min());  
    return toReturn;  
}
```
